Vertical coordinate information is referenced to the *insert datum name (and abbreviation) here, for instance, "North American Vertical Datum of 1988 (NAVD 88)."*

*Hydraulic Conductivity: The standard unit for hydraulic conductivity is cubic foot per day per square foot of aquifer cross-sectional area ($ft^3/d/ft^2$). In this report, the mathematically reduced form, feet per day (ft/d), is used for reference. Likewise, transmissivity, which is the hydraulic conductivity multiplied by the saturated thickness of the aquifer, is expressed in the form square feet per day (ft^2/d).

Geohydrology and Simulation of Ground-Water Flow in Ohio River Alluvial Aquifers near Point Pleasant, Lubeck, Parkersburg, Vienna, Moundsville, and Glendale, West Virginia

By Mark D. Kozar *and* Kurt J. McCoy

Abstract

Ground-water flow was simulated for four areas in alluvial aquifers bordering the Ohio River in western West Virginia. The four ground-water-flow models included well fields for the Point Pleasant, Camp Conley, Lubeck, Parkersburg, Vienna, Moundsville, and Glendale public water systems. The models were developed to assess the direction and rate of ground-water flow to public supply wells in the well fields and to assess the effects of large ground-water withdrawals on the ground-water-flow system. The models can be used by water resources managers to develop source-water protection areas for the public supply wells in the study area and in other Ohio River alluvial aquifers. In addition, results of this investigation may be used to help assess the potential rate and movement of nonreactive contaminants in emergency situations, such as a chemical release resulting from a railway or highway accident. Many of the well fields discussed in this report are near transportation corridors and chemical manufacturing facilities.

The alluvial aquifer along the Ohio River has the capacity to yield millions of gallons of water per day to wells completed either in the banks of the Ohio River or as lateral collectors extending beneath the river. Withdrawal of large quantities of ground-water by pumping wells completed in the alluvium can result in large cones of depressions, alter normal flow patterns, and induce infiltration of water from the river towards pumping wells. During high-water events, such as floods, the normal hydraulic gradient can be temporarily altered, and flow to the alluvium from the river can be induced.

Glacial outwash deposits of sand and gravel form the primary aquifer that is tapped as a source of ground water not only for public water systems but also for use by industry, agriculture, commercial facilities, and in rare instances, by residential home owners. Fluvially deposited fine-grained silts and clay, deposited mostly as a result of floods, typically overlie the glacial outwash deposits and form a confining layer. The glacial outwash and fine-grained silt and clay layers form a series of terraces in the alluvium between the Ohio River and the nearby Pennsylvanian and Permian-age bedrock uplands.

Recharge to the alluvium can occur from several sources including seepage from adjacent bedrock, leakage from overlying tributary streams, induced infiltration of water from the Ohio River as a result of pumping, flow from the river to the alluvium due to a reversal of hydraulic gradient during floods, and from precipitation falling on the alluvium. Recharge from adjacent bedrock and leakage from overlying tributary streams was negligible. Induced infiltration of river water and precipitation are the major sources of recharge to the alluvial aquifer. Induced infiltration of water from the Ohio River accounted for various amounts of water pumped from the following well fields: Parkersburg (75 percent), Glendale (72 percent), Moundsville (50 percent), Lubeck (39 percent), Vienna (7 percent), and Point Pleasant (4 percent) well fields. The remainder of the recharge was from precipitation falling on the alluvium. None of the water withdrawn from the Camp Conley well field is derived from infiltration of river water.

Generally, the composition of alluvial sediments along the Ohio River between Huntington, West Virginia and Pittsburgh, Pennsylvania become coarser further to the north. Because the glacial outwash deposits in alluvial flats in the northern part of the study area were closer to the Laurentide Ice Sheet, they are coarser grained than those in the alluvial flats further to the south. Consequently, the hydraulic conductivity of alluvial aquifers to the north (300 to 500 ft per day (ft/d)) are typically higher than those to the south (75 to 300 ft/d).

Introduction

Commercial and industrial facilities, many cities, and some domestic residences rely on the high-yielding alluvial aquifers of the Ohio River for public and industrial water supplies. Wells in this area commonly produce several hundred to thousands of gallons per minute (gpm) of water. Four of he state's largest public ground-water supply systems, which are in Marshall, Mason, and Wood Counties, rely on wells that penetrate the alluvial terraces of the Ohio River. The alluvial terraces consist of poorly to well-sorted sand, silt, clay, and gravel deposits overlying river-scoured Pennsylvanian or Permian-age bedrock. In such highly permeable sediments, numerous sources pose potential threats to ground-water supplies, including pesticides and nitrates from agriculture, pathogens such as bacteria and viruses from leaking sewer lines and septic systems, and industrial chemicals from production and processing plants. In addition, numerous transportation corridors cross the area including railroads, highways, and barge traffic on the Ohio River. Numerous industrial chemicals as well as petroleum products commonly are transported along these corridors

and could pose potential threats to ground-water supplies if spilled within well-capture zones.

In 1996, amendments to the Safe Water Drinking Act (U.S. Environmental Protection Agency, 2004) were passed to address growing concern of possible contamination of drinking-water sources. This mandate, enforced by state and federal regulatory agencies, required public ground-water- supply systems to delineate recharge areas as part of the Wellhead Protection Program. Most of the recharge and wellhead protection areas (WHPAs) in the study area had been previously delineated by the West Virginia Bureau for Public Health- Office of Environmental Health Services (WVBPH-OEHS) using simplified analytical ground-water-flow models. Although such simplified analytical models provide a good first approximation of potential WHPAs, they typically cannot effectively simulate ground-water flow in complex hydrogeologic settings. Numerical ground-water-flow modeling using three dimensional models such as the U.S. Geological Survey (USGS) MODFLOW (McDonald and Harbaugh, 1988) software, provides a tool from which more accurate simulations of ground-water flow and delineations of WHPAs can be developed. In 2001, the USGS began a project to develop ground-water-flow models in cooperation with the WVBPH-OEHS. The major objective of this investigation was to assess ground-water-flow rates and directions in alluvial aquifers in four areas along the Ohio River in the western part of West Virginia. The project spanned from January 2001 through December 2003.

Purpose and Scope

This report presents results from four separate numerical ground-water-flow models of alluvial aquifers along the Ohio River. The models simulate ground-water flow rates and directions and were used to estimate the contribution of water to municipal well fields either from recharge to the alluvium or from induced infiltration of water from nearby streams in Point Pleasant, Lubeck, Parkersburg, Vienna, Moundsville, and Glendale, West Virginia. Five-year time-of-travel zones based on particle tracking are included to assist water-resources managers in delineating source-water protection areas for the public water systems in the modeled areas. Because this report incorporates the likely maximum and minimum extremes in permeability of alluvial sediments likely to be encountered along the entire West Virginia reach of the Ohio River, the results of this study may be applicable to similar alluvial aquifers along the Ohio River in West Virginia, Pennsylvania, and Ohio as far south as Ironton, Ohio.

To determine ground-water-flow directions and time of travel to public water supplies in alluvial aquifers along the Ohio River, some components of the computer program Visual MODFLOW version 2.8.2 (Waterloo Hydrogeologic, 2000) were used. The software is a commercially derived graphical user interface to the USGS MODFLOW-96 three-dimensional finite-difference ground-water-modeling software (Harbaugh and others, 1996). The software also provides an interface to MODPATH (Winston, 1999), which is a USGS particle-tracking program. Visual MODFLOW was used to simulate ground-water flow and to provide estimates of hydraulic head in the aquifers analyzed. Ground-water-flow directions, rates of flow, effects of ground-water withdrawal, and hydrologic budgets were simulated with the Visual MODFLOW software. Particle tracking, using the MODPATH module of the program, was conducted to estimate flow paths to individual public supply wells.

The models within this report were primarily developed from existing data, especially data from contamination investigations conducted in support of U.S. Environmental Protection Agency (USEPA) RCRA (Resources Conservation and Recovery Act) and CERCLA (Comprehensive Environmental Response, Compensation, and Liability Act) investigations. Due to budget and time constraints, only minimal field data was collected during the course of the investigation, mainly to provide water-level and stream-flow data in areas where such data was not available. A large quantity of aquifer test, well log, water level, and other data was also available from USGS databases and published reports. Finally, well construction, pumpage, and other hydrogeologic data were retrieved from each specific water plant included within this report.

The primary objective of the study was to estimate the rate and direction of ground-water flow by numerical simulation of the alluvial aquifer. A second objective was to simulate ground-water-flow paths to public supply wells using particle-tracking software. These preliminary ground-water-flow models will provide data and information to water-resources managers that will help them delineate wellhead protection areas for public supply wells.

Previous Investigations

Early ground-water-flow models of the Ohio River alluvium include digital simulations of drawdown in Kentucky by Grubb, (1975) and Kernodle, (1977). A steady-state and transient model of ground-water flow in the Louisville, Kentucky area was completed by Lyverse and others (1991). Unthank (1996, 1998) and Unthank and Nelson (1999) modeled alluvial aquifers in northwestern Kentucky to estimate hydraulic properties, recharge, and discharge to the Ohio River. In a three-layer model, the Corporate Remediation Group (2003) simulated ground-water flow at an industrial site in Washington Bottom, West Virginia to evaluate and predict ground-water flow under various pumping stresses. Burgess and Niple (1996) modeled seven scenarios in the Little Hocking, Ohio area to determine WHPAs and to evaluate the fate and transport of potential contaminants in the aquifer. CDM (2002a) prepared a ground-water-flow model for the Vienna area to assess the potential transport of perchloroethylene (PCE) in the aquifer.

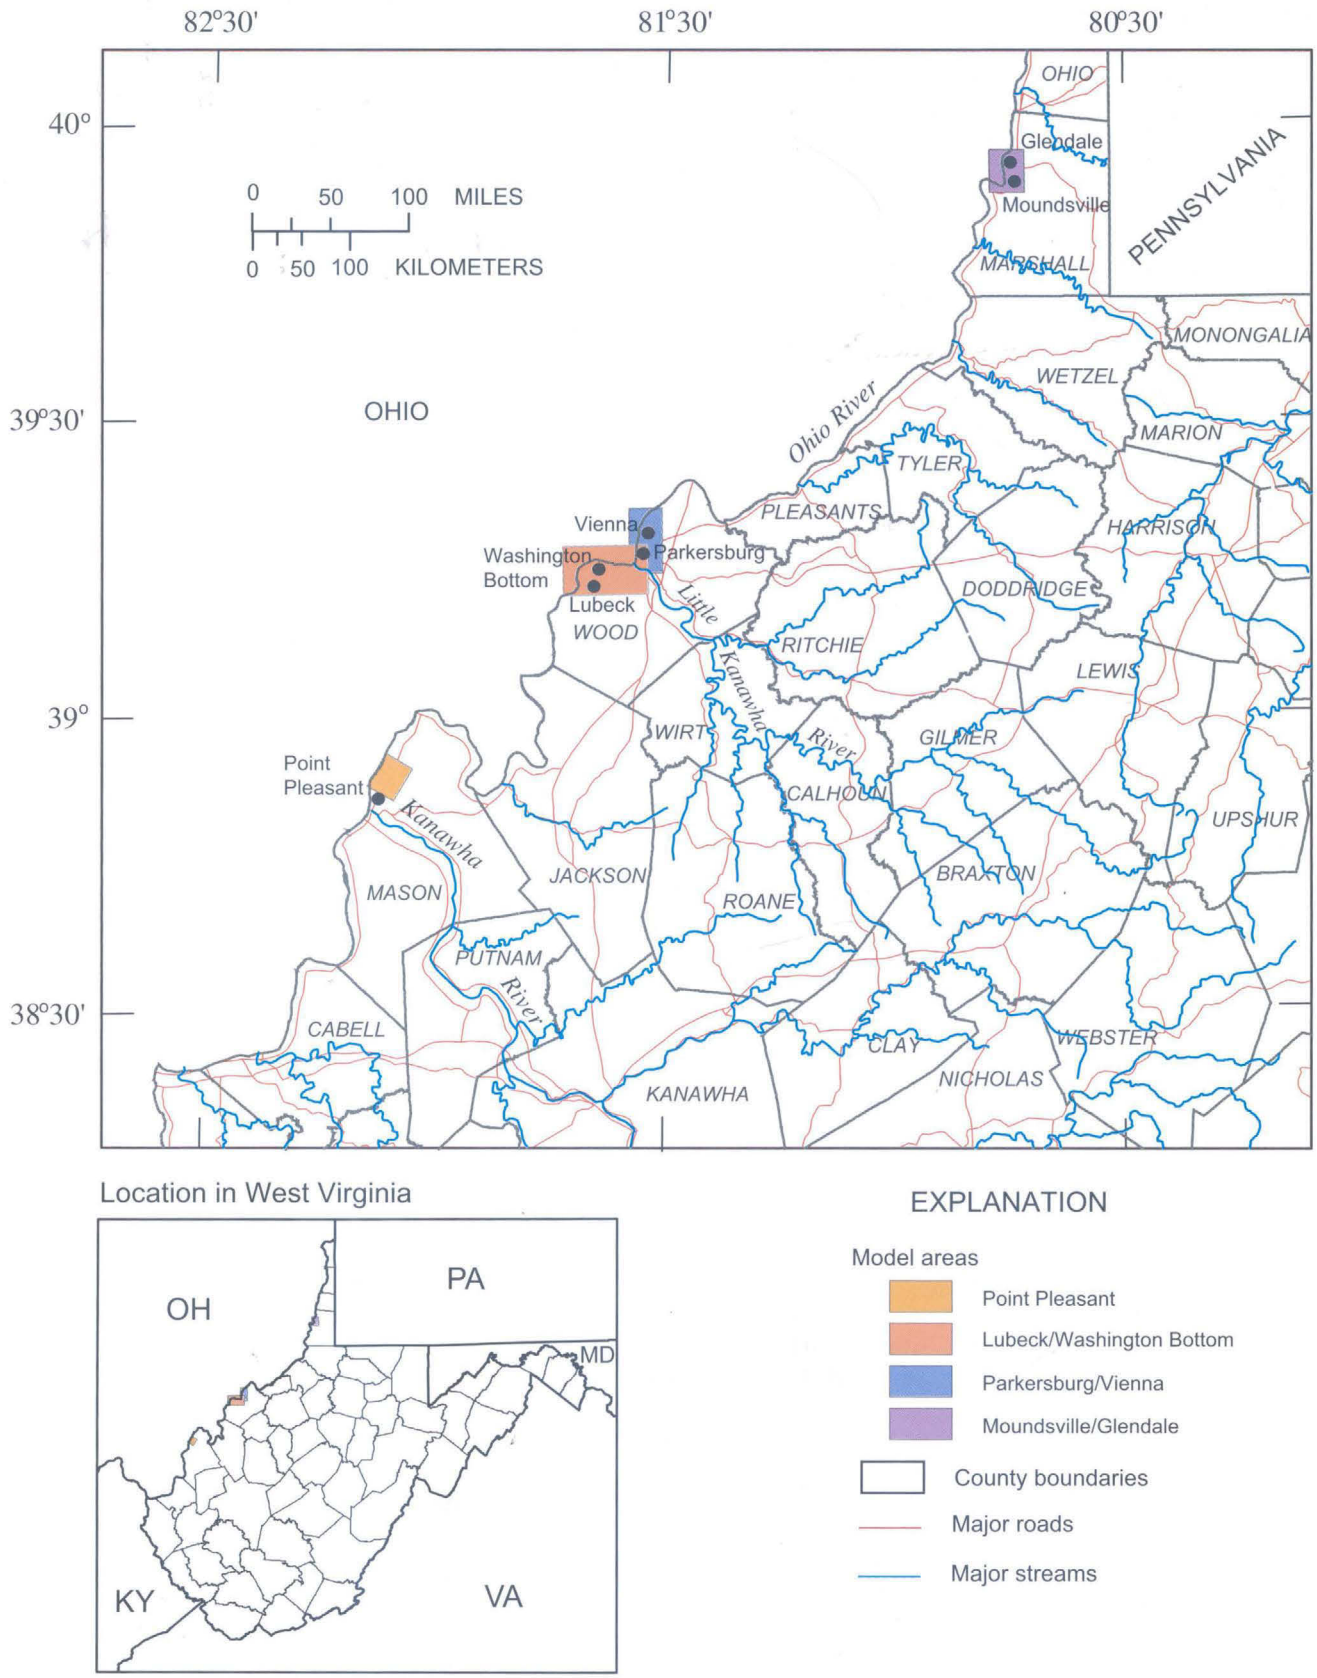

Figure 1. Locations of study areas where ground-water flow was simulated, West Virginia.

Description of Study Area

Four alluvial river terraces along the Ohio River, commonly referred to as bottoms, were identified for modeling of ground-water flow to public ground-water-supply systems (fig. 1). Bottom areas are defined as low-lying, flat alluvial deposits along past and present river floodplains. Descriptions of each area are from Carlston and Graeff (1956). The modeled areas are all in the alluvial sand and gravel deposits of the Ohio River and its terraces and extend over a 166-mile (mi) reach of the Ohio River from Point Pleasant in Mason County to Glendale in Marshall County, West Virginia.

Point Pleasant

The Point Pleasant Bottom in Mason County, West Virginia, is 12.5 mi long from the mouth of the Kanawha River near the City of Point Pleasant. At its widest point, abandoned river channels extend into the surrounding bedrock hills for up to 2.8 mi. Normal pool stage of the river in the area is 538 ft. Records from 29 wells in the northern areas show about 30 to 40 ft of sands and gravels overlying the bedrock surface. The sands and gravels are overlain by clays, sands, and sandy clays. In the southern areas, clays and sandy clays cover sands and gravelly sands 25 to 48 ft thick. In the area immediately adjacent to the Point Pleasant well field, confining units typically are absent, and the aquifer is more or less unconfined. Three well tests conducted in the area indicated saturated thicknesses of 28 to 41 ft and a mean hydraulic conductivity of 340 ft/d (Cross and Schemel, 1956).

Lubeck/Washington Bottom

Also called Washington Bottom after original owner George Washington, the Lubeck Bottom is 5.2 mi long and 0.7 mi wide and is in Wood County, West Virginia. The wooded, rural area includes land used for agriculture, chemical and plastic production, and a 250-acre closed solid-waste landfill. The Ohio River normal pool elevation in the area is approximately 582 ft. Test borings show basal sands and gravels 19 to 77 ft thick overlain by 14 to 35 ft of clays, sandy clays, and silts. Thicker sands and gravels are found under higher terraces. An aquifer test conducted by the USGS yielded an estimated hydraulic conductivity of approximately 334 ft/d (Cross and Schemel, 1956).

Parkersburg/Vienna

The Parkersburg/Vienna Bottom extends north 6.5 mi from the mouth of the Little Kanawha River. Its width is 0.8 mi, narrowing toward the small town of Vienna. Normal pool elevation at the dam is approximately 582 ft. Parkersburg and Vienna are just north of the Lubeck/Washington Bottom area and are also in Wood County. Three test borings at the dam show fine to coarse sands and gravels 25-27 ft thick, overlain by loam and clay in places. At the Parkersburg well field, the alluvium thins to about 60 ft, containing 15 to 25 ft of permeable sands and gravels overlain by varying thicknesses of fine sand, silt, and clay (Jeffords, 1945). Overlying clays and silty clays are generally 5 to 15 ft thick. Aquifer tests conducted at four locations in the Parkersburg area indicate a mean hydraulic conductivity near 850 ft/d and saturated thickness of approximately 21 ft (Cross and Schemel, 1956). Land use on the alluvium in Parkersburg and Vienna is highly developed with numerous commercial and industrial facilities and residential homes.

Moundsville/Glendale

The Moundsville/Glendale Bottom is a cut-off meander channel extending 3.5 mi along the Ohio River in Marshall County, West Virginia. The predominantly residential Glendale occupies the relatively narrow (0.5 mi wide) northern part of the bottom. By comparison, a broad circular southern part at Moundsville has a width of more than 3 mi. Normal pool stage of the Ohio River in the area is approximately 623 ft. Well depths range from 70 to 100 ft and wells are known to have penetrated 100 ft of gravel near the middle of the meander (Cross and Schemel, 1956). Pumping rates above 100 gal/min are typical for industrial wells drilled in the thick gravel bed. Saturated thicknesses generally range from 30 to 40 ft.

Geohydrology

The geology of the four study areas is typified by highly permeable sand and gravel glacial outwash deposits. The deposits have the capacity to yield millions of gallons of water per day to wells, especially to wells completed in river-bank deposits or completed as long, horizontal, radial-collector wells extending beneath the river bed. Residents of the Ohio River Valley have been withdrawing water from wells completed in these sediments since the mid-to late 1800's.

Geology

Alluvial aquifers of the Ohio River have been of interest for more than 100 years. Hennen (1909), Grimsley (1910), and Krebs (1911) provided county reports with detailed geologic information including lithologic, stratigraphic, and structural data of the study area along the Ohio River. Deutsch and others (1966) published a comprehensive survey of ground-water resources for the Ohio River Basin and several of its larger tributaries. The West Virginia Geological and Economic Survey (WVGES) produced a three-part report including a description of Ohio Valley geology in West Virginia by Cross and Schemel (1956) and ground-water resources of the Ohio Valley in West Virginia by Carlston and Graeff (1956).

The Ohio River follows a gentle gradient along the border between West Virginia and Ohio for 277 mi before it reaches

Kentucky. Hilly terrain of south-southeast dipping Lower Permian and Pennsylvania-age rocks is dominant in the upland areas and gives way to a flood plain less than 500 ft below. Lower Permian and Pennsylvanian bedrock consists of cyclic groups of interbedded sandstones, shales, limestones, clays, and coals (Cross and Schemel, 1956). Local rises in bedrock elevation have been ascribed to changes from older limestone strata to younger more resistant sandstones (Cross and Schemel, 1956).

Pleistocene alluvium from glacial outwash deposits of the pre-, early-, and late-Wisconsinan age have been reworked and deposited at lower elevations forming terraces (Simard, 1989). Carlston and Graeff (1956) found the maximum thickness of the alluvium beneath the highest terraces is 120 ft, and that the thickness of the alluvium generally decreases in the downstream direction.

Pleistocene sands and gravels directly overlying the bedrock surface are thought to be the result of continental glaciation of the northern Ohio River headwaters. Jeffords (1945) suggested these sediments are from 15 to 25 ft thick in well-fields in the Parkersburg area. Pleistocene sand and gravels in Marshall County to the north are similar in thickness (Cross and Schemel, 1956). Hall (1917) found sediments in Parkersburg to be firmly cemented in the 18 in. above bedrock.

Heterogeneous alluvial deposits ranging from gravels to clays overlie the Pleistocene glacial deposits. Generally, the alluvium thickens away from valley walls and near the mouth of tributary streams. North of Parkersburg, the alluvial fill consists mainly of gravels, sands, and gravelly sands whereas fine sands, silts, and clays dominate sediments downstream from Parkersburg. Lenticular interbeds of varying composition are not uncommon throughout the alluvium (Cross and Schemel, 1956). Surface sediments consist of fine-grained sands to silts and clays of Holocene age and average 10 ft in thickness, sometimes up to 40 ft in the flood plain (Cross and Schemel, 1956). This poorly permeable layer serves to limit recharge from precipitation, and in places acts as a confining layer (Cross and Schemel, 1956). Simard (1989) identified a sequence of five river terraces formed as the channel shifted back and forth cutting into the Wisconsinan deposits. Three flood plains also were identified. Radiocarbon ages of the fluvial and alluvial sediments ranged from 5,000 years to more than 40,000 years (Simard, 1989).

Hydrology

The high-yielding alluvial aquifers of the Ohio River Valley have been extensively studied. Jeffords (1945) was one of the first to investigate the effect of river stage on ground-water levels in the adjacent alluvium. He concluded that a large amount of recharge to the alluvial aquifer was derived from the river when the Ohio River was at high stage. Induced infiltration from the Ohio River to pumping wells in the aquifer is likely where such wells are close to the river, although local heterogeneity of river-bottom sediments may reduce the connection (Mathes and others, 1995; Jeffords, 1945). Tributaries to the Ohio River may provide additional recharge as they flow across alluvial and fluvial deposits (Mathes and others, 1995).

Recharge from tributary streams to underlying alluvial aquifers in the region has not been well quantified. Discharge was measured at two tributary streams during this investigation both at the point where the streams flowed onto the alluvium and at a second point just prior to discharge to the Ohio River. Both streams are characteristic of streams which flow across alluvium and discharge to the Ohio River. The change in flow was not appreciable between upstream and downstream sites on either stream. This may indicate that tributary streams are armored to a certain extent suggesting tributary recharge is negligible in most cases. Also, throughout the region, ground-water levels typically are far below the base of tributary streams and significant gains or losses to and from streamflow are not anticipated.

In the absence of significant recharge from tributary streams and from bedrock, the majority of recharge under ambient conditions is likely from precipitation. A large percentage of precipitation is lost to surface runoff and evapotranspiration. Evapotranspiration in the Louisville, Kentucky, area accounted for 65 percent of precipitation; the remaining 35 percent was almost equally divided between infiltration and runoff (Rorabaugh, 1949). Infiltration from the river can occur naturally when local hydraulic gradients are reversed during high river stages, which is common during floods, typically in winter and spring. Under base-flow conditions, however, hydraulic gradients generally are from the alluvium towards the river. Discharge from surrounding bedrock aquifers serves as an additional source of recharge but is likely small in comparison to that derived from precipitation (Mathes and others, 1995).

In a survey of 183 wells in Ohio River alluvium of West Virginia, Kozar and Mathes (2001) found an average saturated thickness of 35.6 ft and average static water level of 43 ft below land surface. Well yields ranged from 30 to 5,500 gal/min. In a test of 19 wells, transmissivity of the aquifer ranged from 130 to 1,750 square ft per day (ft^2/d) with average saturated thickness of 25 ft between Parkersburg and Point Pleasant (Carlston and Graeff, 1956). Transmissivity ranged from 540 to 59,000 ft^2/d in wells analyzed by Kozar and Mathes (2001). The same report provided a median storage coefficient of 0.20 for Ohio River alluvium, indicative of an unconfined aquifer. Mean transmissivities of 750, 4,200, and 7,500 ft^2/d were reported by Corporate Remediation Group (2003), Mathes and others (1995), and Burgess and Nipple (1996), respectively.

Ground-Water Levels and Flow Directions

Ground-water levels vary throughout the alluvium but generally indicate a hydraulic gradient towards the Ohio River under normal conditions (Kazmann and others, 1943). Under normal pool conditions, in the absence of significant pumping, hydraulic gradients are almost exclusively towards the river. Exceptions occur during floods or other high-water events.

When the stage of the Ohio River increases markedly over a short period of time such as during a flood, a reversal in the normal hydraulic gradient occurs and river water can flow into and recharge the alluvium. These effects usually are very short in duration and are not believed to significantly alter the hydrologic budget in the alluvium; however, such effects may have pronounced effects on the flow of contaminants in the alluvium. In addition, large pumping centers can cause very large cones of depression to form, which may result in lowering the water level in the aquifer to levels below that of the normal pool stage of the Ohio River.

Ground-Water Recharge

Estimates of ground-water recharge for alluvial aquifers bordering the Ohio River are highly variable. An early estimate of recharge for the alluvial aquifer near Louisville, Kentucky was 9.2 inches per year (in/yr) (Rorabaugh, 1949). Estimates of recharge for bedrock aquifers in the region based on streamflow hydrograph analysis ranged from 6.7 to 9.6 in/yr (Kozar and Mathes, 2001), or 16 to 24 percent of the average annual precipitation of 40.7 in. (NOAA, 2002) at Parkersburg. Recharge rates for alluvial aquifers with little silt or clay could be potentially much higher. A calibrated ground-water-flow model for the Vienna area from prior modeling studies indicated recharge rates in the range from 6.9 to 11.5 in/yr (CDM Corporation, 2002b). Results of calibrated ground-water-flow models in the Washington Bottom area near Lubeck ranged from 4 in/yr on Holocene flood plains to 20 in/yr in colluvial deposits near the margins with upland bedrock outcrops at the edge of the valley (Corporate Remediation Group, 2003). A test conducted in the Weirton area for a large collector well assumed a recharge rate of approximately 11.4 in/yr (Ranney Corporation, 1981). In the wellhead protection plan for the Little Hocking, Ohio, well field, a recharge rate of 12 in/yr was assumed (Burgess and Niple, 1996). Estimates of ground-water recharge for alluvial aquifers along the Ohio River in West Virginia applied to models in this report range from 0.1 to 11.8 in/yr (Table 1) and vary based on the composition of the alluvium in certain areas. Alluvial deposits with a high percentage of sand and gravel tend to have recharge rates approaching 12 in/yr whereas deposits with a large percentage of silt and clay may be as low as 3 in/yr.

In addition to recharge from precipitation, the alluvial aquifers along the Ohio River also may receive significant infiltration directly from the Ohio River and possibly to a minor extent from tributary streams crossing the alluvium (Jeffords, 1945). As previously discussed, induced infiltration can take place under two scenarios, either when the cone of depression for a pumping well lowers water levels in the aquifer to depths below the stage of the Ohio River or when the normal hydraulic gradient is reversed due to flooding or high river stages. Induced infiltration of water directly from the Ohio River can contribute the majority of water yielded to wells, especially from large collector wells, which may far exceed that possible from precipitation alone.

Table 1. Recharge rates used in ground-water-flow simulations of various alluvial aquifer settings.

[in/yr, inches per year]

Description of model areas	Recharge rate (in/yr)
Parkersburg/Vienna Area	
Parkersburg well field and lower terraces	6.0
Parkersburg upper terraces	3.0
Vienna Wellfield	9.0
Point Pleasant Area	
Point Pleasant oxbow	11.0
Point Pleasant well field and lower terraces	12.0
Lubeck Area	
Lubeck well field	7.0
Washington Bottom upper terraces	9.8
Blennerhassett Island	11.0
Reworked Ohio River bottom sediments	0.1
Moundsville/Glendale Area	
Moundsville well field	11.0
Glendale well field	11.0

Aquifer Characteristics

Aquifer characteristics are hydraulic properties of aquifers and include transmissivity, hydraulic conductivity, saturated thickness, storativity, porosity, and depth to water. For alluvial aquifers along the Ohio River, existing data and reports were compiled and used for simulating ground-water flow and for particle tracking. The alluvial aquifers bordering the Ohio River vary in the composition of sediments but generally share many common characteristics. All the aquifer characteristics used for the simulations described in this report are listed in table 2. The only aquifer characteristic that changes to a significant degree in the alluvium is hydraulic conductivity. Because glacial outwash deposits in the northern part of the study area are composed of coarser grained sediments than the alluvial deposits further to the south, the transmissivity and hydraulic conductivity of alluvial flats to the north typically are higher than those to the south. Fine-grained flood-plain sediments of fluvially deposited silt and clay overlie the coarser grained glacial outwash deposits in many areas (Simard, 1989).

Ground-Water Withdrawals

Ground water is withdrawn from Ohio River alluvial aquifers for many purposes including public water supplies, public-service water districts in rural areas, irrigation of crop land, industrial water for processing, power-plant cooling water, and less commonly, for small commercial and domestic supplies. For this investigation, ground-water-flow models were developed mostly for large municipalities in Point Pleasant, Lubeck, Parkersburg, Vienna, Moundsville, and Glendale, West Virginia and for the Camp Conley Public Service District in Mason County. Average rates of ground-water withdrawal for these systems and the few smaller point sources near these well fields are listed in table 3.

The largest public supplier in the study area is the City of Parkersburg that withdraws approximately 4,800,000 gallons per day (gal/d) of water and the smallest supplier is the Camp Conley Public Service Water District which withdraws only 34,000 gal/d. Two large chemical manufacturing facilities in the area immediately north of the Lubeck well field withdraw approximately 8,800,000 gal/d and 2,060,000 gal/d, respectively. Such large withdrawals are common for industrial sites along the Ohio River and include facilities that manufacture steel, plastics, chemicals, and other products.

Simulation of Ground-Water Flow

Ground-water flow for four distinct alluvial aquifers that border the Ohio River in West Virginia was simulated for this investigation. The modeled areas from south to north are 1) Point Pleasant in Mason County, 2) Lubeck and Washington Bottom in Wood County, 3) Parkersburg and Vienna in Wood County, and 4) Moundsville and Glendale in Marshall County. The four model areas are in an approximate 150-mi stretch of the Ohio River in West Virginia. Where appropriate, model simulations include parts of the alluvial aquifer in Ohio. This was done to assess the effects of pumping centers on either side of the Ohio River on the hydraulic head distribution throughout the aquifer. Large pumping centers on one side of the Ohio River may affect head distribution in the alluvial aquifer on the opposing bank if large amounts of water are withdrawn from the aquifer. This is the case for the Lubeck/Washington Bottom and the Parkersburg/Vienna models. Pumping in the Point Pleasant and Moundsville/Glendale areas was not sufficient to have major effects on head distributions in the aquifer. Also, alluvial sediments are not exposed on the Ohio side of the river in these areas.

Conceptual Models

The conceptual model of ground-water flow for the four areas outlined in this report is fairly straightforward. Because the alluvial materials are primarily sand and gravel with overlying deposits of silts and clays, the aquifer is expected to be homogenous. Some variability between vertical and hydraulic conductivity is expected due to stratification in the aquifer as thin lenses of clay or sand are commonly interspersed in the sand and gravel aquifer matrix. Overall, flow in the aquifer should meet assumptions of Darcian flow.

Flow to the aquifer is possible from several sources including infiltration of precipitation (recharge), bedrock seepage, direct infiltration from the Ohio River during floods, and leakage from tributary streams crossing alluvial sediments. For the areas described in this report, seepage from bedrock aquifers was not considered a major source of inflow because the hydraulic conductivity of bedrock aquifers in the region is typically low when compared to that of the alluvial aquifers. Seepage from bedrock aquifers was therefore not simulated in any of the models. Although infiltration of flood waters from the Ohio River may be a source of water to the aquifer, under normal conditions most ground water discharges to the river. Where pumping wells are near the river, induced infiltration of water directly from the river is common. Seepage from overlying tributary streams to the underlying alluvial aquifer is considered minimal based on discharge measurements made during this investigation and the fact that most tributary streams in the modeled areas were dry for substantial periods during this investigation. Precipitation is therefore the main source of recharge to the alluvial aquifers.

Of the 40.7 inches of precipitation (NOAA, 2002) that typically falls annually on the area, 9-12 in. may be expected to infiltrate and recharge alluvial aquifers, with lesser amounts of recharge in areas characterized by thick sequences of silt and clay. The remaining 28.7 to 31.7 in. of precipitation is either lost to streams as surface runoff or lost to evaporation or transpiration by plants. For bedrock-dominated streams in the region, total streamflow averages 18.7 (in/yr). Of the 18.7 in/yr, approximately 11.7 in. (29 percent) is attributed to baseflow discharge and 7 in. (17 percent) is attributed to surface runoff. Evapotranspiration would therefore account for approximately 22.0 in. (54 percent) of the precipitation lost annually. Most recharge takes place in the colder months from November through April when evaporation and transpiration by plants are minimal. Only minor amounts of ground-water recharge typically occur in the warmer months under normal conditions.

Under normal conditions, ground water is expected to flow from upland terraces towards the Ohio River or adjacent tributary streams (Kazmann and others, 1943). This flow pattern can be altered by two processes. First, large cones of depression may form around pumping centers withdrawing large volumes of water (Kazmann and others, 1943). This large cone of depression would be expected for large water systems withdrawing millions of gallons of water per day. Smaller systems that only withdraw a few tens of thousands of gallons of water per day that would have flowed to the river would not be expected to produce cones of depressions large enough to cause a significant flow of water from the river into the alluvium. The second process that may alter the typical ground-water-flow gradient are high water events, especially during floods. During a high-water event on the Ohio River, water levels in the aquifer

would be expected to rise to above normal levels. This would result in a temporary reversal of the normal gradient and cause water to infiltrate the alluvium from the adjacent Ohio River. These events are short in duration (typically only a few days) and result in only a temporary change in the hydraulic gradients in the alluvium. Water levels would return to normal quickly after the Ohio River stage had receded to normal pool stage.

Numerical Models

Visual MODFLOW Version 2.8.2 (Waterloo Hydrogeologic, Inc., 2000) was used in this study to simulate ground-water flow. This program incorporates MODFLOW-96 (Harbaugh and McDonald, 1996), which is a three-dimensional ground-water-flow model, and MODPATH (Winston, 1999), which is a particle-tracking routine. Both software packages were developed by the USGS. Visual MODFLOW is an enhanced version of MODFLOW-96 that includes MODPATH with additional graphical user interfaces attached to aid model use.

The normal assumptions with regard to ground-water flow in porous media were considered applicable to the study area. Ground-water flow is assumed to be laminar. The aquifers simulated were also assumed to be homogenous and isotropic in representative cells; on a larger scale, local variability in aquifer properties has a negligible effect on the overall rate and direction of simulated ground-water flow. Stratified lenticular deposits of silt and clay occur locally in the aquifer and result in a horizontal hydraulic conductivity that is several times more permeable than in the vertical direction. Although this difference between horizontal and vertical hydraulic conductivity has not been quantified in the study areas, a horizontal-to-vertical hydraulic conductivity ratio of approximately 10:1 was used for all ground-water simulations.

All simulations of ground-water flow for this investigation were developed as steady-state models. Transient effects were not considered to be a major concern, because the models did not incorporate storage or solute transport. Transient effects, such as rising stages on the Ohio River, have an effect on ground-water flow but their occurrence and duration are so infrequent and short that a steady-state model can effectively simulate ground-water flow for the four modeled areas. However, estimates of the 5-year time-of-travel paths to public supply wells were made as part of the steady-state models developed for this investigation. The modeled areas were generally selected where extensive pre-existing hydrogeologic data sets were available. Data-collection activities were kept to a minimum due to the large amount of available data for most study areas. Field data-collection activities performed during this project concentrated on investigating hydrologic processes that were poorly understood, such as the effect of tributary streams, and on compiling well construction, maintenance, and pumping records from the major public, industrial, and commercial water suppliers in the modeled areas. Only the Moundsville/Glendale and Parkersburg areas required field investigations to document water levels for calibration purposes.

Particle-tracking routines used in this investigation require data on aquifer porosity. Unfortunately, few data are available documenting the porosity of sediments in alluvial deposits along the Ohio River. Nevertheless, the sediments are similar to many sand and gravel deposits in other areas in the country. Average porosity for alluvial sediments generally ranges from 25 to 50 percent for sand and gravel and from 35 to 70 percent for silt and clay (Freeze and Cherry, 1979). Values of porosity of 25-30 percent were applied to coarse-grained sediments. Values of 30-35 percent were applied to fine-grained sediments to construct the ground-water-flow models.

Point Pleasant

The Point Pleasant model extends from the Bellmeade area on the north side of Point Pleasant, West Virginia near Ohio River mi 262. north to Eightmile Island and Ohio River mi 256. (fig. 2). The model area includes the Bellmeade area of Point

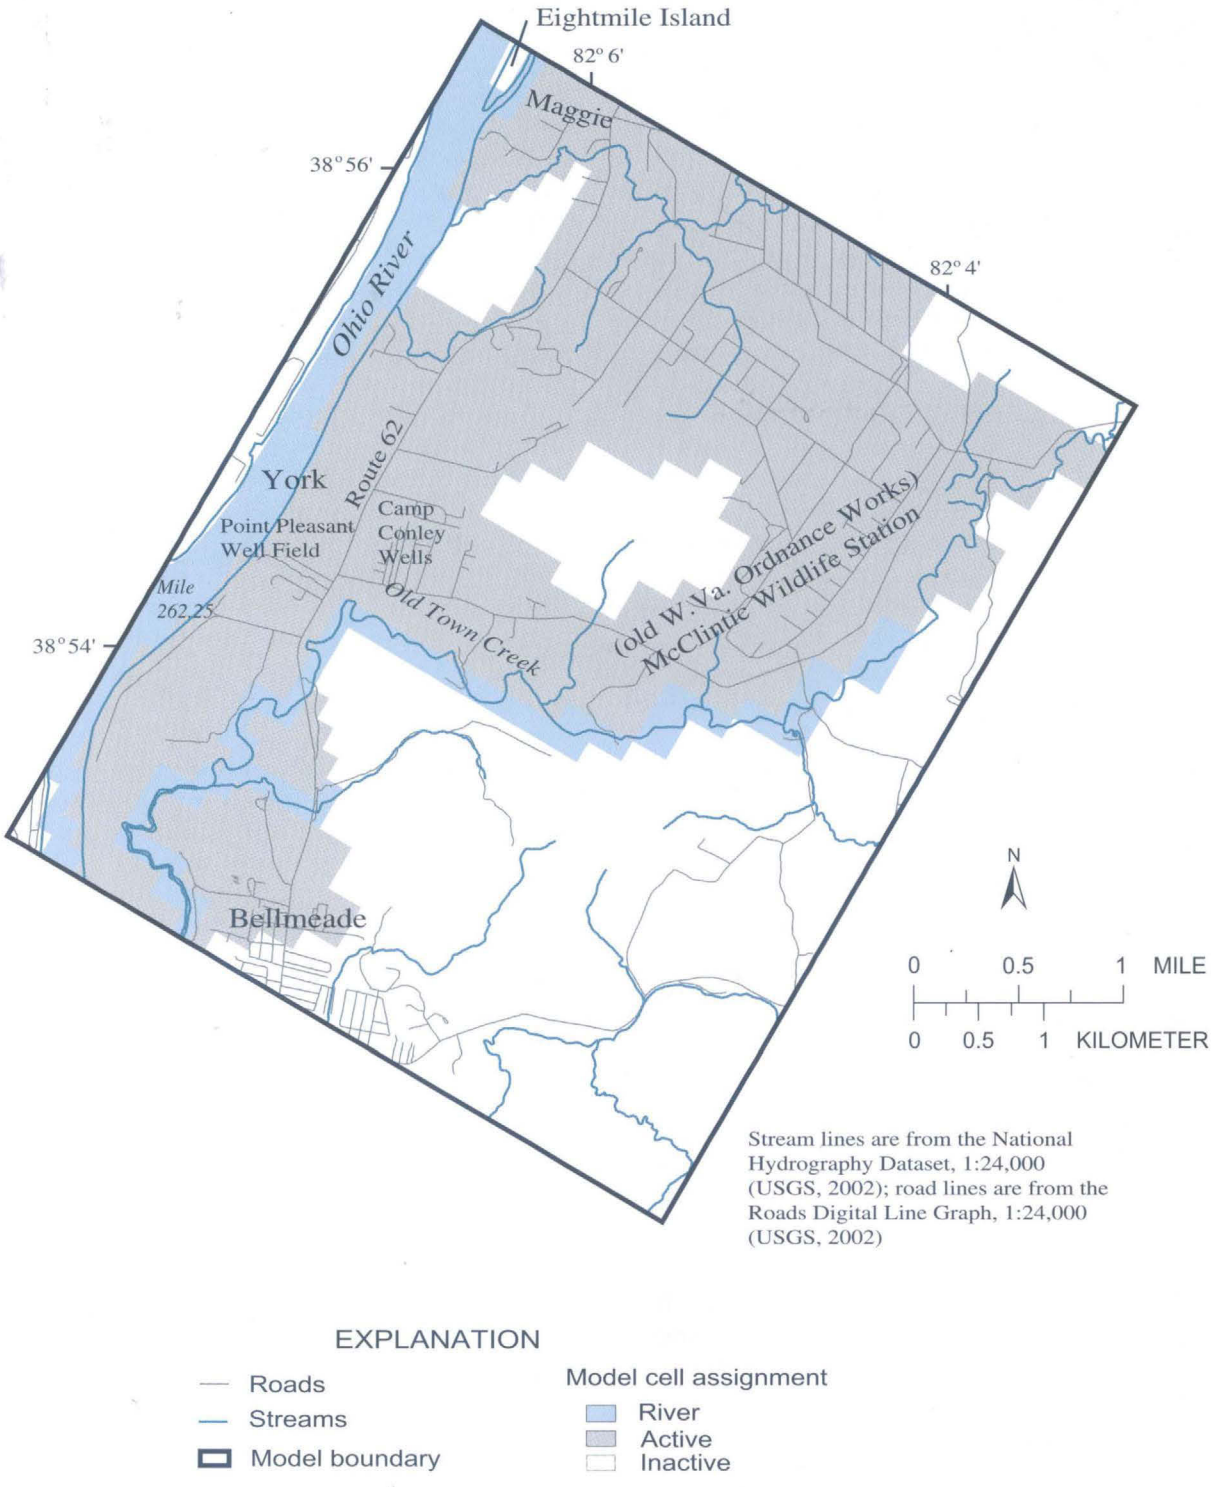

Figure 2. Location of the Point Pleasant model area, West Virginia (refer to figure 1 for general location map).

Pleasant, the southern part of the community of Maggie, the McClintic Wildlife Management area, and the Point Pleasant and Camp Conley Public Service District (PSD) well fields. A large part of the area once comprised the Point Pleasant Ordnance Works where explosives were manufactured during World War II (Kazmann and others, 1943).

Ground-water and soil contamination have been documented at several locations near the Point Pleasant and Camp Conley PSD well fields, primarily resulting from activities at the old Ordnance Works and a nearby manufacturing facility (Peter Costello, West Virginia Department of Environmental Protection, written commun., 2000). As a result of the ground-water and soil contamination at these primary sites, several hydrogeologic assessments have been conducted in support of USEPA RCRA and CERCLA investigations. A site-wide hydrogeological study of the Point Pleasant Ordnance Works (IT Corporation, 1996) included borehole logs, water-level measurements, aquifer tests, and water-quality data. An initial hydrogeologic assessment of the facility was conducted by the USGS during World War II to provide for expansion of operations (Kazmann and others, 1943). Additional data obtained included Ohio River depth soundings and bottom maps (Kent Browning, U.S. Army Corps of Engineers, written commun., 2000) and borehole logs and pumping records for the Point Pleasant Water Plant (Dan Rogers, Point Pleasant Water Department, written commun., 2000). Additional data used to calibrate and develop the ground-water-flow model for the Point Pleasant and Camp Conley areas were obtained from the files of the West Virginia Department of Environmental Protection (Peter Costello, written commun., 2000), including borehole geophysical logs and water-level data for the U.S. Army Reserve Center, and borehole logs and water levels for the manufacturing facility.

Boundary Conditions and Layers

Boundary conditions for the Point Pleasant model were different than for any of the other models presented in this report. In the Point Pleasant area some alluvial sediments were deposited in an old meander cutoff (oxbow) of the Ohio River. This oxbow has not been documented in the past, but borehole records indicate two sequences of sand and gravel separated by an intermediate layer of silt and clay. The Point Pleasant model was therefore designed as a three-layer model to simulate the effects of the intermediate silt and clay layer in the old meander cutoff. Layer 3 represents the sand and gravel alluvial aquifer from an elevation of 475 to 510 ft (fig. 3). Layer 2 extends from 510 to 570 ft and represents the intermediate silt and clay layer (also shown on fig. 3). The uppermost layer (layer 1) extends from 570 ft to land surface and represents the uppermost sand and gravel layer (fig. 4). Layer 2 essentially is not present in the area occupied by the alluvial aquifer adjacent to the Ohio River. The layers slope to higher elevations in the eastern part of the model to represent thinning of the alluvium in upland areas.

Generally, the area adjacent to the river is characterized by a fairly homogenous layer of sand and gravel. The northern part of the sand and gravel alluvial aquifer is less permeable than the southern part. It is likely that the knob of bedrock in the area to the north of the alluvial aquifer prevented the accumulation of large deposits of the more permeable sands and gravel whereas the southern part of the aquifer was exposed to reworking of sediments by the force of the Ohio River. As a result, a hydraulic conductivity of 83 ft/d was assigned to the northern part of the alluvial aquifer and a value of 350 ft/d was assigned to the southern part of the alluvial aquifer. The composition of sediments in the old meander cutoff is similar to that in the northern part of the alluvial aquifer and was assigned hydraulic conductivities (77 to 87 ft/d) similar to that for the northern part of the alluvial aquifer. The intermediate silt and clay layer was assigned a hydraulic conductivity of 0.1 ft/d.

The model consists of 59 rows and 28 columns and includes 1,652 cells (fig. 4). Approximately one third of the cells represent areas with bedrock outcrops and are inactive cells in the model. The model encompasses an area of 19,087 by 23,585 ft or approximately 16.1 square miles (mi^2). The major boundary conditions of the model consist of river cells along the Ohio River and tributary streams and inactive cells in areas where bedrock crops out. A variably spaced model grid was used with a finer density of cells in the areas of the model near active pumping wells and a coarser grid in areas of the model of less relevance. As in the other models, simulation of ground-water seepage from adjacent bedrock aquifers was considered unnecessary. Oldtown Creek is the only major tributary in the model area. Discharge measurements were made on Oldtown Creek at two locations, one in the headwaters of the basin and a second near the bridge on route 62. There was no appreciable increase or decrease in flow across the alluvial flat, indicating little interaction of the stream with the underlying alluvial aquifer.

Because there was no overlying confining unit, recharge to the alluvium in the Point Pleasant area was greater than that for either the Lubeck/Washington Bottom or Parkersburg/Vienna areas. For the model, recharge was set at 12 in/yr in the alluvial aquifer bordering the Ohio River and 11 in/yr in the area occupied by the old meander cutoff (fig. 5). Attempts to lower recharge rates below 11 in/yr were unsuccessful because the model could not calibrate to known heads with lower recharge rates.

Model Calibration and Limitations

The model of ground-water flow for Point Pleasant was calibrated by matching measured and simulated water levels. Of the four areas described in this report, the Point Pleasant area had the largest set of aquifer-characteristic data for model development and calibration. A total of 23 wells provided water-level data for model calibration. Model calibration goals were to match simulated to observed heads within 15% of the overall range in water level within the aquifer (about + or - 4.2 feet). This is considered acceptable as water-level data was not collected as part of this investigation and the model is based entirely on existing data. Of the 23 wells used for model calibra-

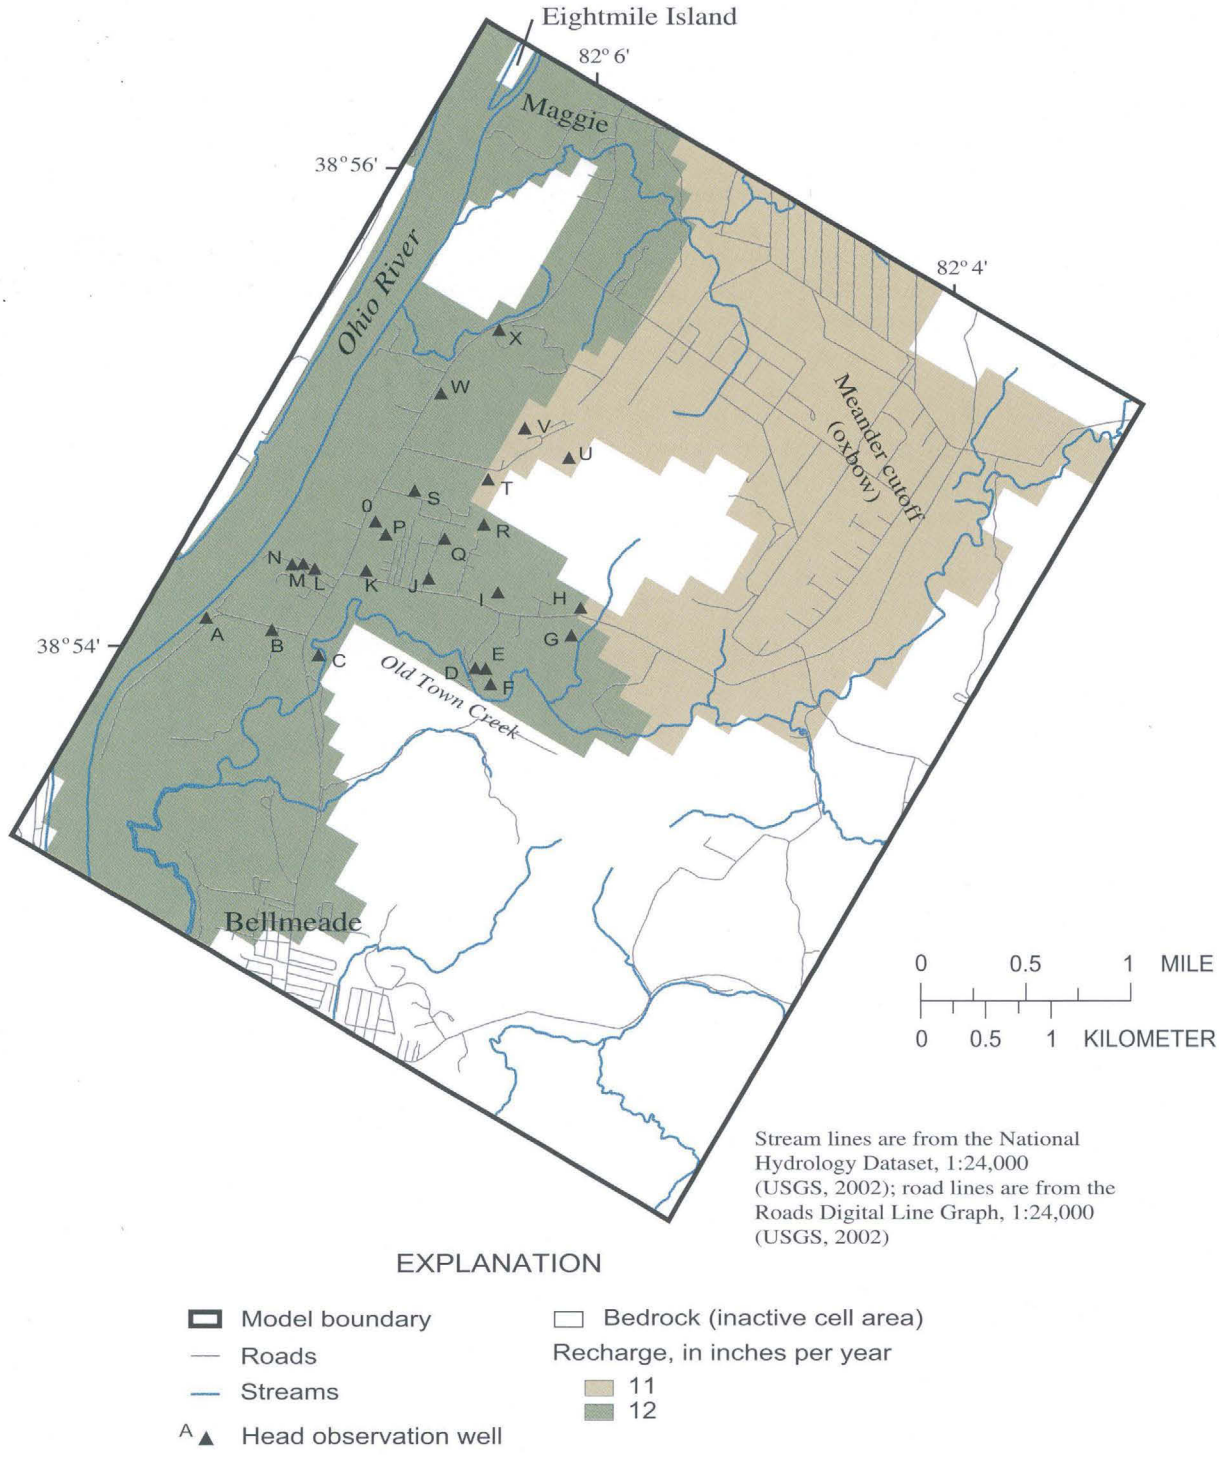

Figure 5. Head observation wells and recharge assigned to the upper layer of the Point Pleasant model.

tion, only 3 failed to meet the 4.2 ft error criteria and most wells calibrated to within a few feet of observed water levels. The calibrated model had a mean error of -1.41 ft and a root mean-squared error of 3.80 ft. Most of the error was from wells in and near areas where the hydraulic conductivity changes significantly over short distances. In these areas, it is difficult to match simulated water levels to observed water levels. Fortunately, these areas are not adjacent to the active public supply wells, and the errors do not significantly affect the simulation of ground-water flow to the major pumping centers. Overall the model calibrated well and compared favorably to a potentiometric surface map prepared for the area in support of contamination investigations in the area (IT Corporation, 1996).

Potential limitations that could affect the accuracy of the simulation are mostly related to a lack of data in the uppermost regions of the potential recharge area to the public supply wells. Fortunately, data were sufficient to characterize the areas near the public supply wells. Additional data, especially borehole logs and water levels, would be needed to better refine the hydrogeology in the easternmost area of the model.

Model Analysis and Interpretation

Other than a few domestic wells that pump minimal quantities of water, the major ground-water withdrawals in the Point Pleasant well field and surrounding area are from the city of Point Pleasant well field and the wells at the Camp Conley PSD (fig. 6). Simulated flow paths indicate that none of the water pumped from the Camp Conley wells originates from the Ohio River. The 5-year time-of-travel area is less than 0.25 mi in length, and derives most of its recharge from an area primarily to the east of the wellfield. The Point Pleasant and Camp Conley well fields derive water from the same general area and a change in the pumping schedule of one would likely cause a change in the flow paths and time of travel to the others. The degree of the change would be proportional to the rate of change in pumping.

Results of the simulations conducted for the Point Pleasant well field indicate that only a minimal amount of water, approximately 4 percent, is derived from river bed infiltration of water from the Ohio River. Most water (96 percent) is derived from a large circular area approximately 5,000 ft by 4,700 ft that surrounds the Point Pleasant well field. The 5-year time-of-travel area is approximately 0.84 mi^2. The contaminated land to the south is in the cone of depression surrounding the Point Pleasant well field and some wells on the southern side of the Point Pleasant well field have tested positive for trace amounts of contaminants.

Lubeck/Washington Bottom Area

The study area for the Lubeck/Washington Bottom ground-water-flow model extends from Ohio River mi 195 near Meldahl to Ohio River mi 190 to the north and incorporates part of Blennerhasset Island (fig. 7). The model area includes the Lubeck well field and two chemical manufacturing plants in Washington Bottom. The modeled area is very large (approximately 23 mi^2) and was designed to be much larger than the expected recharge area to the Lubeck well field.

The model area was extended to these limits for two reasons. First, a surfactant, commonly known as C8 has been used in production processes at the chemical plant (chemical plant #1) in the northern portion of Washington Bottom for a number of years, and some C-8 was released into the Ohio River and to the atmosphere as part of normal plant operations. Several wells in the Little Hocking well field showed traces of C-8 contamination; this led to an investigation to determine the extent and severity of the potential contamination. A ground-water-flow model was prepared to assess potential movement of C-8 from the plant area (Corporate Remediation Group, 2003). The high density of data available for the areas encompassing chemical plant #1 and another nearby chemical manufacturing facility (chemical plant #2) provided a clear boundary condition for the model and extensive data for model development and calibration.

In addition to the data collected for the C-8 investigation, a wealth of data was available from prior studies: (1) hydrogeologic investigations at the two chemical plants in Washington Bottom (Michael P. Sherrier - URS Corporation, written commun., 2001 and Peter Costello, W.Va. Department of Environmental Protection, written commun, 2000); (2) a wellhead protection area report for the Little Hocking, Ohio well field (Burgess and Niple, 1996); (3) hydrogeologic evaluations for additional water supply from Blennerhasset Island (Burgess and Niple, 1988; Leggette, Brashears, and Graham, 1986); and (4) investigations of bedrock geology for a part of the corridor D highway project and bridge crossing Blennerhasset Island just south of Parkersburg and at the north end of Washington Bottom (Ronald L. Adams, H.C. Nutting, written commun., 2002). Well records also were obtained for the Lubeck PSD (James Cox, Lubeck PSD, written commun. 2001).

Boundary Conditions and Layers

Boundary conditions for the Lubeck/Washington Bottom model are complex and have several constraints. The stratigraphy of the alluvium in the Lubeck area is complex; however, sediments can generally be categorized as glaciofluvial deposits of sands and gravels overlain by finer-grained fluvial deposits of silt and clay, many of which were deposited during floods (Carlston and Graeff, 1956). As such, the model design for the Lubeck area is composed of only two layers, a lower layer (fig. 8) representing more permeable sand and gravel deposits and an upper layer (fig. 9) representing finer grained silt and clay deposits. The model consists of 95 rows and 101 columns and includes 9,595 cells (fig. 8) and encompasses approximately 23 mi^2. Due to the sinuous shape of the study area, nearly half of the cells in the model are inactive cells (fig. 9) and the model actually only simulates ground-water flow over an area of approximately 12 mi^2.

There is a great deal of variability in the hydraulic conductivity, especially in the upper silt and clay layer (table 2).

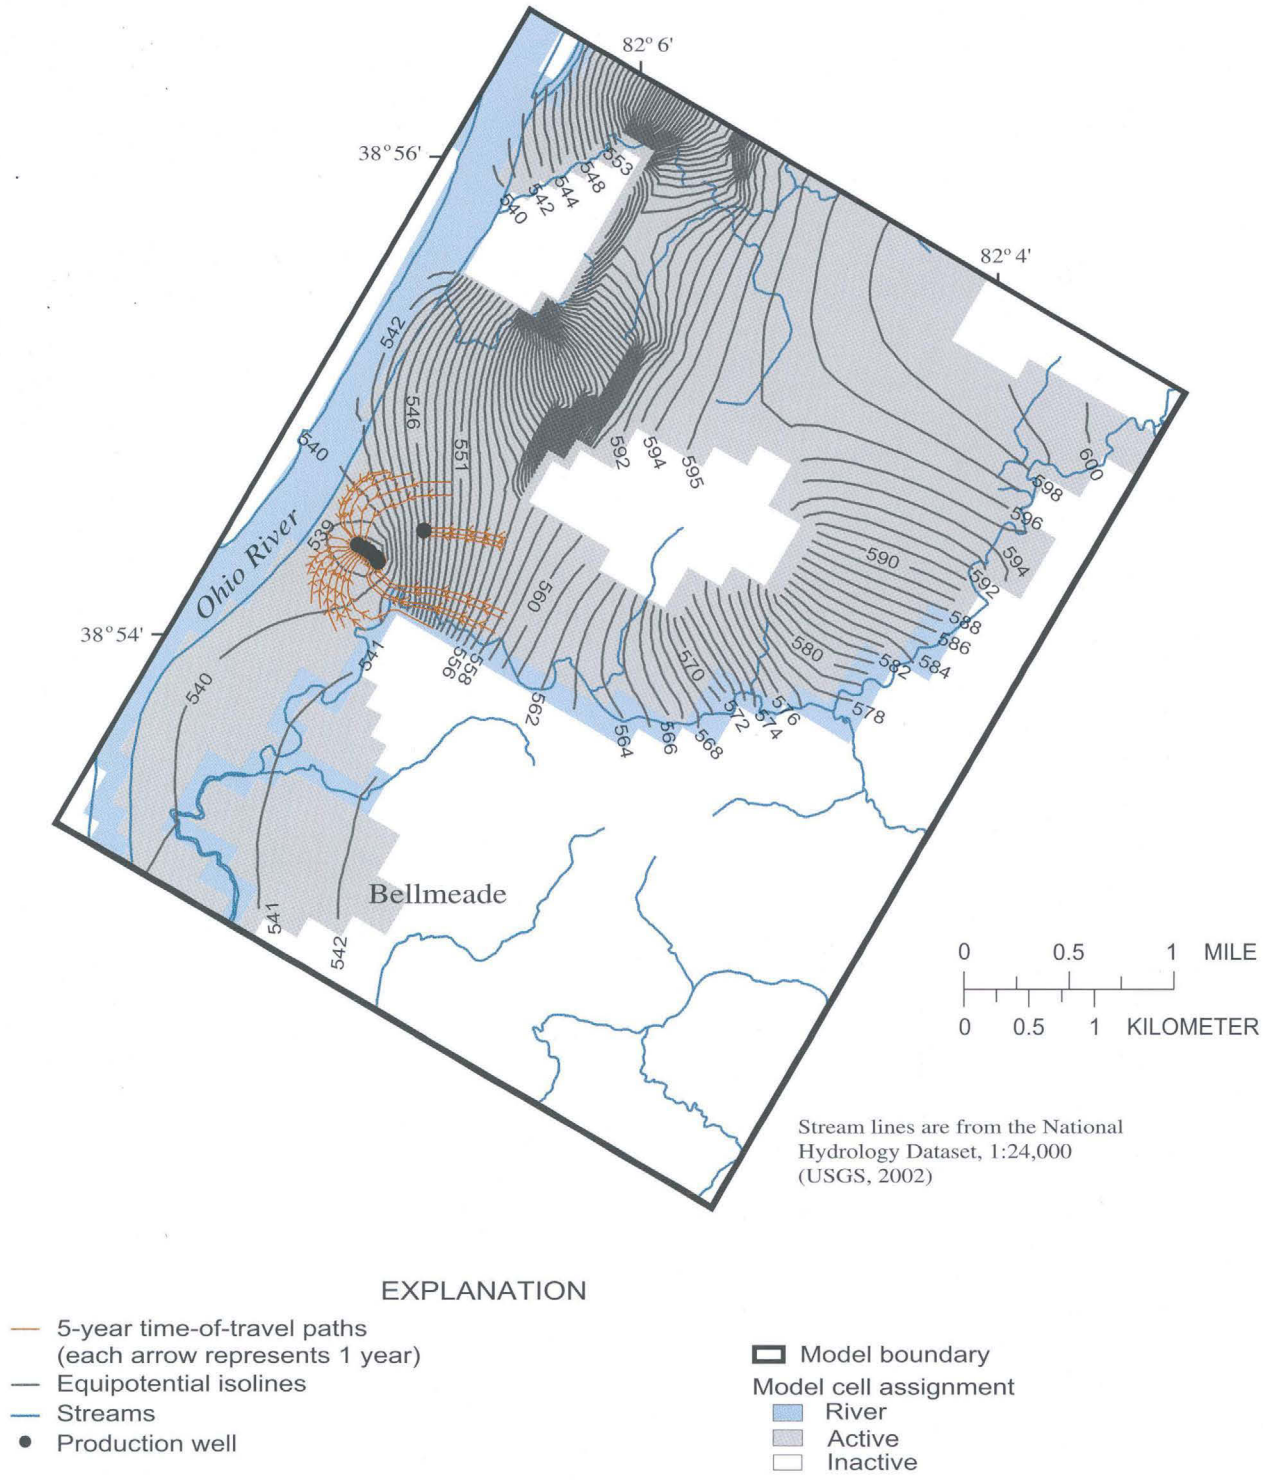

Figure 6. Calibrated heads and 5-year time-of-travel paths to the Point Pleasant well field in the lower layer (layer 3) of the model.

Figure 7. Location of the Lubeck/Washington Bottom model area, West Virginia (refer to figure 1 for general location map).

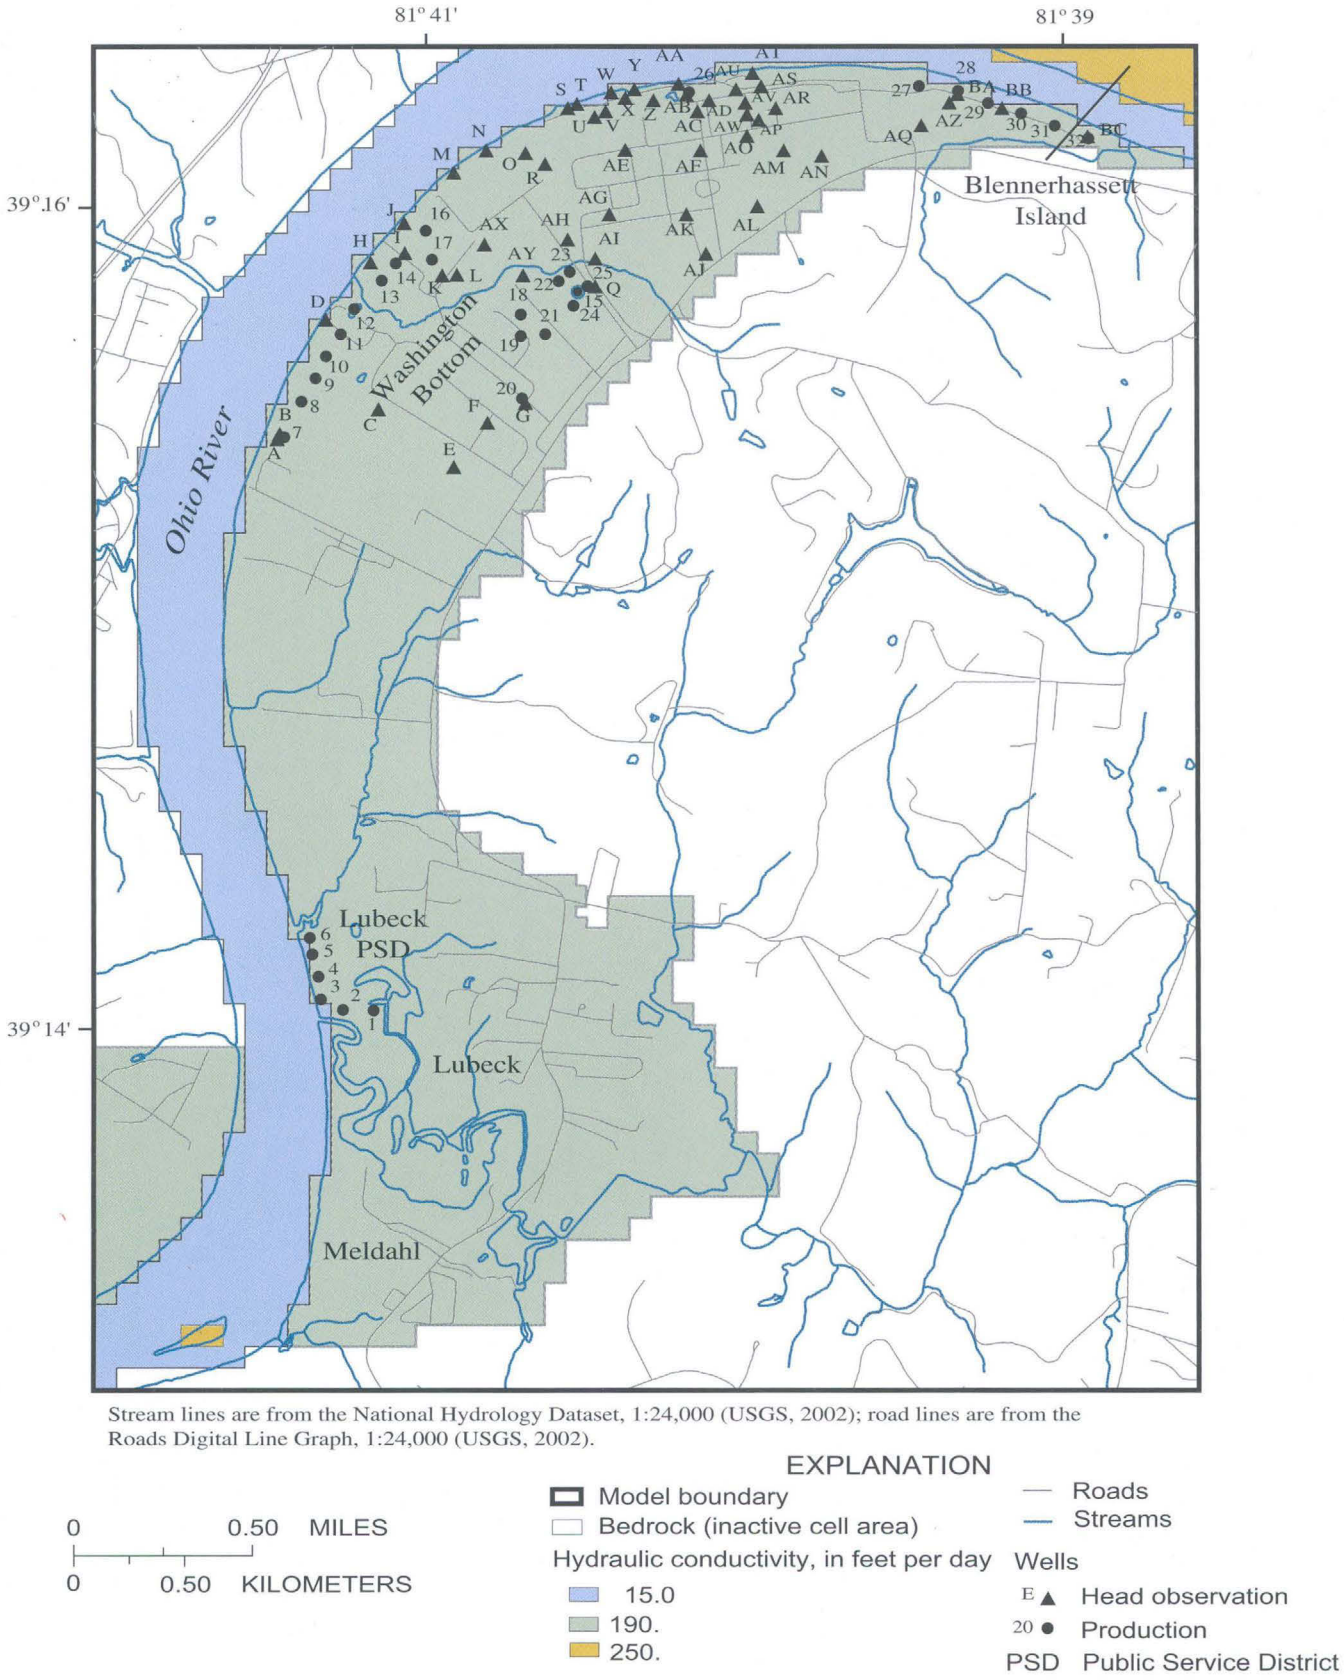

Figure 8. Values of hydraulic conductivity and location of production and head observation wells in the lower layer of the Lubeck/Washington Bottom model.

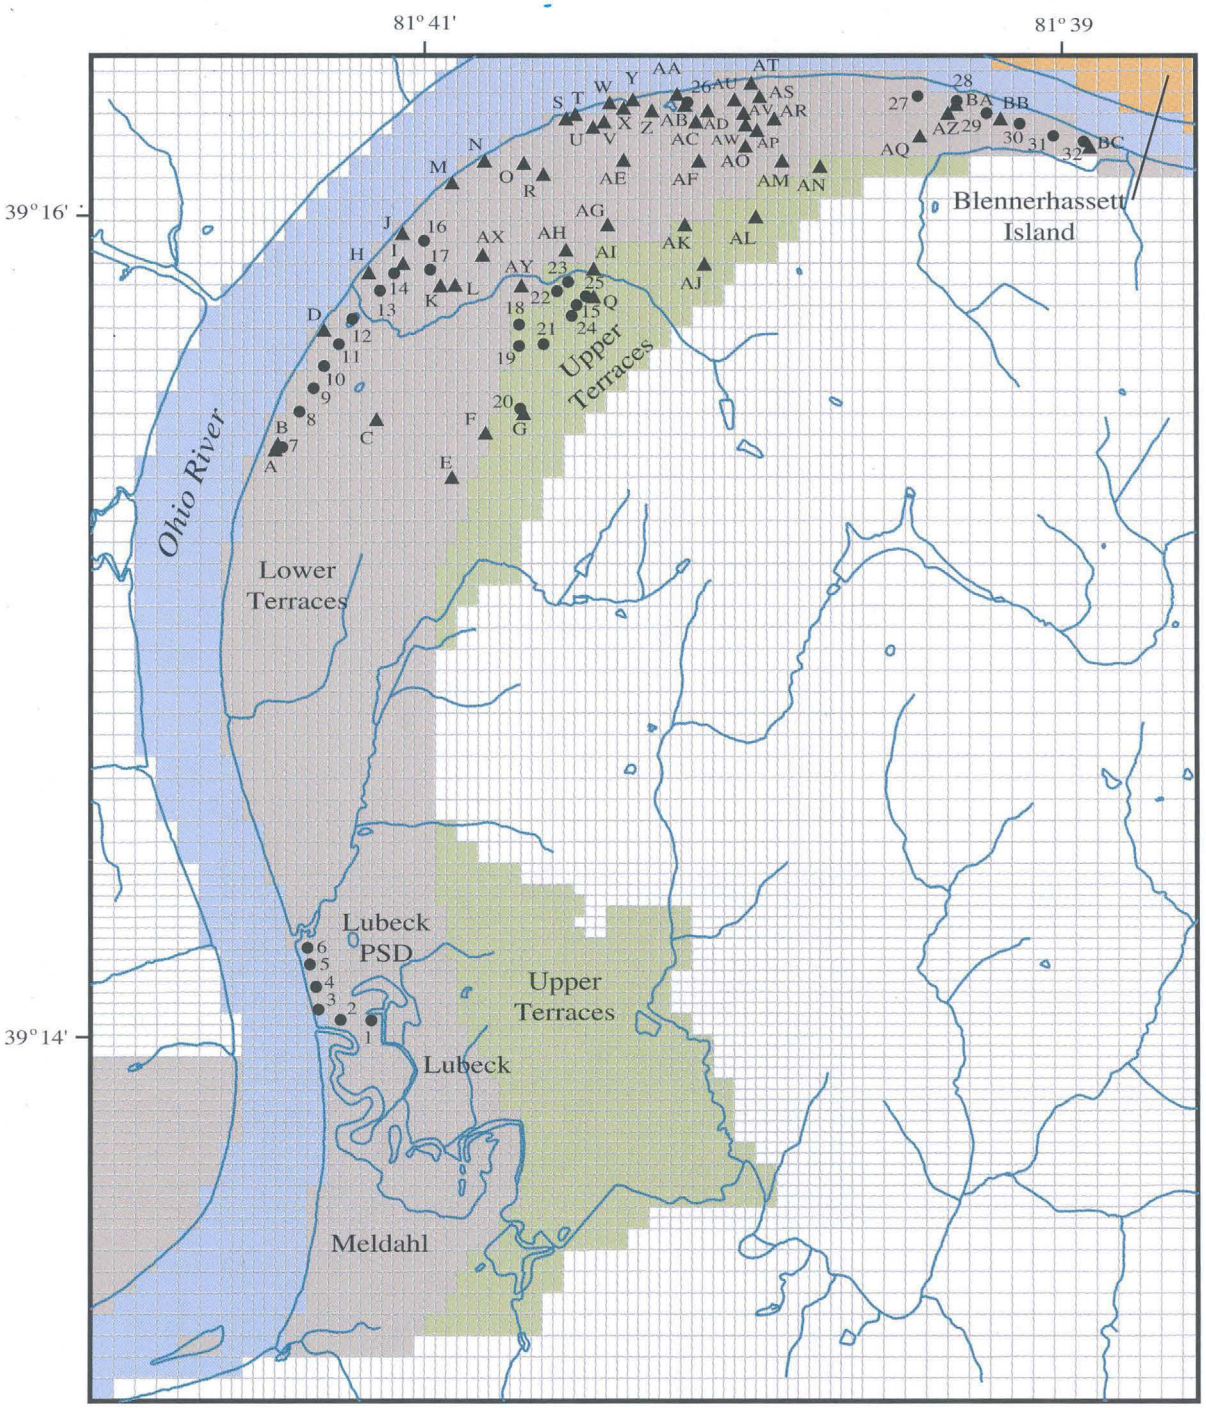

Figure 9. Well locations, model grid, inactive cells, and values of hydraulic conductivity in the upper layer of the Lubeck/Washington Bottom model.

Hydraulic conductivity based on prior published estimates is complex for the model area. Generally, the lower alluvial aquifer was simulated from an elevation of 530 to 570 ft and assigned a hydraulic conductivity of 190 ft/d. The upper confining layer representing fluvially deposited silts and clays was simulated from 570 ft to land surface and assigned a hydraulic conductivity of 1.0 ft/d. The uppermost terraces are composed primarily of permeable sands and colluvium and assigned a hydraulic conductivity of 190 ft/d, similar to that for the deeper aquifer.

Only alluvial sediments were included in the modeled area, and surrounding bedrock areas were not incorporated. This approach is valid because of the extreme variability in hydraulic conductivity for alluvial aquifers in the area compared to bedrock aquifers. The transmissivity of alluvial aquifers in the area ranged from 2,100 to 59,000 ft^2/d with a mean of 9,400 ft^2/d (Kozar and Mathes, 2001). Bedrock aquifers in the area have transmissivities averaging only about 130 ft^2/d (Kozar and Mathes, 2001). Thus, the low transmissivity of bedrock aquifers would result in negligible inflow of ground water to the alluvial aquifer from bedrock.

Results of the ground-water-flow model for this study were compared with the previous model developed for the Lubeck area that incorporated bedrock areas (Corporate Remediation Group, 2003), and no discernible difference between the models was found. This comparison indicates that simulation of ground-water flow in Ohio River alluvial sediments does not require inclusion of flow from bedrock areas and also indicates that ground-water flow to the alluvium from bedrock is minimal.

River cells and no-flow cells were the two primary boundary conditions used in the design of the Lubeck model. The Ohio River was simulated with a series of river cells and included a large backwater wetland area near the Lubeck well field. No-flow cells were set at the margin between the bedrock and the alluvium. During the course of this study (January 2001 to December 2003), the modeled areas experienced severe drought. As a result, no flow was visible in any of the tributary streams flowing from bedrock onto the alluvium. Seepage measurements could not be made to assess the effect of ground-water seepage to or from these tributaries. Discharge measurements made in the Parkersburg/ Vienna and Point Pleasant areas as part of this investigation (to be discussed later in this report) did not indicate appreciable flow either from or to the tributary streams, and the minimal seepage from the streams would have had a negligible effect on the overall water budget even if present. The few tributary streams in the area were therefore not specifically included in the model using either river or drain cells. If flow had been present in the streams, it is likely that only a minor component could have infiltrated to the underlying alluvial aquifer.

Recharge was assigned to the upper layer (fig. 10) on the basis of the relative permeability of sediments at the surface. The area occupied by the lower terraces was assigned a recharge of 7 in/yr and the colluvial deposits in the area were assigned a recharge of 9.8 in/yr. Alluvial sediments on Blennerhasset Island generally were more permeable and were assigned a recharge of 11 in/yr.

Model Calibration and Limitations

One major modification to the model was necessary to provide an accurate simulation of ground-water flow in the area. An influx of fine-grained sediments deposited by large volumes of water from the Little Kanawha River into the Ohio River has apparently resulted in significant reworking of the sediments in the Ohio River immediately downstream of the confluence with the Little Kanawha River. Thus, the hydraulic conductivity of sediments in the Ohio River immediately downstream from the Little Kanawha River is likely to be much lower than the hydraulic conductivity of river sediments near Parkersburg and Vienna. A previous ground-water-flow model developed to document potential transport of C-8 in the Washington Bottom area (Corporate Remediation Group, 2003) encountered this situation and resolved the problem by adjusting the conductivity of river-bottom sediments.

The ground-water-flow model was calibrated by matching simulated and measured water levels. A total of 76 wells provided water-level data for model calibration. Model calibration goals were to match simulated to observed heads within 15% of the overall range in water level within the aquifer (about + or - 4.5 feet). This is considered acceptable as water level data was not collected as part of this investigation and the model is based entirely on existing data. Of the wells used for model calibration, only 9 of the 76 wells failed to meet the 4.2 ft error criteria and most wells calibrated to within a few feet of observed water levels. The calibrated model had a mean error of 1.59 ft and a root mean squared error of 3.24 ft. Most of the error is due to wells being situated near pumping centers. In these areas, computed water levels in pumping cells reflect the average water level in the cell. The simulated heads of monitoring wells in these cells were slightly higher than those actually observed.

Numerous limitations could affect the accuracy of this simulation. The major limitation is lack of detailed information on the composition of the alluvium near the Lubeck well field. Although substantial data are available from past investigations in Washington Bottom, little data relates to aquifer properties for the area immediately adjacent to the Lubeck well field. In addition, reworking of sediments in the Ohio River downstream from the confluence with the Little Kanawha River has resulted in significant alteration of the hydraulic properties of sediments in the streambed. Unfortunately, the exact nature and properties of the reworked sediments are not known. Finally, the geometry of the alluvial aquifer is poorly understood in the area near the Lubeck well field.

Model Analysis and Interpretation

Results of modeling in the Washington Bottom and the Lubeck well field indicate that the primary source of flow to the Lubeck well field is not derived from the immediate area occupied by the nearby chemical plants (fig. 11). Most flow is derived from the area immediately adjacent to the Lubeck well

field near Vaughts Run and Sandy Creek. Part of the flow to the Lubeck well field also is derived directly from the Ohio River, which could be a source of contaminants. Hydraulic gradients indicate that the water table near the Lubeck well field is actually at a higher elevation than the water table near the chemical plants. The Lubeck well field probably does not receive recharge from the northern part of the Washington Bottom area. Of approximately 665,000 gal of water pumped daily from the Lubeck well field, about 261,600 gal (39 percent) is derived from induced infiltration from the Ohio River and about 403,400 gal (61 percent) is derived from the capture of ground water in the alluvium. The area over which recharge to the alluvium would occur in a 5-year period (5-year time of travel) is approximately 3,320 ft by 4,338 ft or 0.5 mi^2 (fig. 11).

Parkersburg/Vienna Area

The modeled area for the Parkersburg/Vienna model extends from the confluence of the Ohio and Little Kanawha Rivers near Ohio River mi 185 in Parkersburg to the upper end of the alluvial flat at the north end of Vienna near Ohio River mi 178 to the north (fig. 12). The modeled area includes the cities of Vienna and Parkersburg. Both cities are located on the same alluvial flat or river bottom and it was logical to simulate ground-water flow for both sites simultaneously.

Data for the Parkersburg/Vienna area are not as abundant as in the Lubeck/Washington Bottom area. A RCRA investigation was conducted and a ground-water-flow model (CDM, 2002b) was developed to assess the fate and transport of PCE from a long-term discharge at a dry-cleaning operation in Vienna. The RCRA investigation provided a substantial amount of hydrogeologic data (Aaron Frantz, CDM Federal Programs Corporation, written commun., 2001) from which a ground-water-flow model could be developed that encompassed the larger Parkersburg and Vienna area. Water-level measurements were made by USGS personnel in a series of old production wells in the Parkersburg well field; data collected was used for model calibration for the southern part of the model area. Data from the Lubeck/Washington Bottom area was very useful for design and calibration of the Parkersburg/Vienna model. Washington Bottom is less than 2 mi south of the confluence of the Ohio and Little Kanawha Rivers and is hydrogeologically similar to the Parkersburg/Vienna alluvial flat. Extrapolation of data from one site to the other helped model design and calibration for both models.

Boundary Conditions and Layers

The Parkersburg alluvial aquifer is adjacent and similar to the Lubeck/Washington Bottom area with one major exception. The Little Kanawha River flows into the Ohio River at the southern terminus of the Parkersburg/Vienna bottom. Fine-grained sediments from the Little Kanawha River are deposited below but not above the confluence. Therefore, the alluvial sediments in the Parkersburg/Vienna bottom typically have a higher proportion of sand and gravel and a smaller proportion of silt and clay than river bottom deposits in the Lubeck/Washington Bottom area. The assigned hydraulic conductivity of Ohio River bottom sediments was therefore much higher (hydraulic conductivity of 175-300ft/d) for the Parkersburg/Vienna area than for the Lubeck/Washington Bottom area (hydraulic conductivity of 4-15 ft/d). However, the alluvial sediments in the lower glacial outwash terrace deposits in the Parkersburg/Vienna area (hydraulic conductivity of 175-300 ft/d) were not appreciably different from those of the Lubeck/Washington Bottom area (hydraulic conductivity of 190-250 ft/d).

The Parkersburg/Vienna model included two layers, a lower layer (fig. 13) representing glacial outwash sands and gravels and an upper layer (fig. 14) representing primarily fluvial silt and clay flood-plain deposits. The upper silt and clay confining layer was assigned hydraulic conductivities ranging from 1 to 3 ft/d and the lower layer was assigend hydraulic conductivities ranging from 100 to 300 ft/d (table 2). The upper confining unit is common in most of the alluvial terraces along the Ohio River (Carlston and Graeff, 1956). The lower alluvial aquifer was simulated from an elevation of approximately 540 to 600 ft and the upper layer representing fluvial deposits was simulated from 600 ft to land surface. The model consists of 69 rows and 30 columns and includes 2,070 cells (fig. 14). Approximately one-third of the cells represent areas with bedrock outcrops and are inactive in the model. The model encompasses an area of 16,605 by 35,705 ft or approximately 21.3 mi^2.

The two primary boundary conditions used in model development included river cells and inactive cells. Bedrock aquifers have much lower permeabilities than alluvial aquifers and were therefore simulated as inactive cells (fig. 14). Because there was flow in tributary streams during development of the Parkersburg model, and because the effect of these streams on the overall hydrology of the area is unknown, river cells were used to simulate ground-water seepage to and from tributary streams. The interaction between tributary streams and the underlying alluvial aquifer were determined to be minimal.

Recharge for the Parkersburg model ranged from 3 to 9 in/yr (fig. 15) and was assigned to layers according to the permeability of sediments in the terraces. The composition of alluvial sediments in the Vienna area was very different from that in the Parkersburg area. Because the overlying silt and clay deposits are much thicker in the Parkersburg area than in the Vienna area, recharge rates of 6 and 9 in/yr, were assigned to the Parkersburg and Vienna areas, respectively. The upper terraces in the Parkersburg area are characterized by much thinner accumulations of alluvial deposits, with a high percentage of silt and clay, and were assigned a recharge value of only 3 in/yr.

Model Calibration and Limitations

The ground-water-flow model for the Parkersburg/Vienna area was calibrated by matching simulated and measured water levels. A total of 28 wells provided water-level data for model calibration. Model calibration goals were to match simulated to observed heads within 10% of the overall range in water level within the aquifer (about + or - 4.0 feet). This is considered

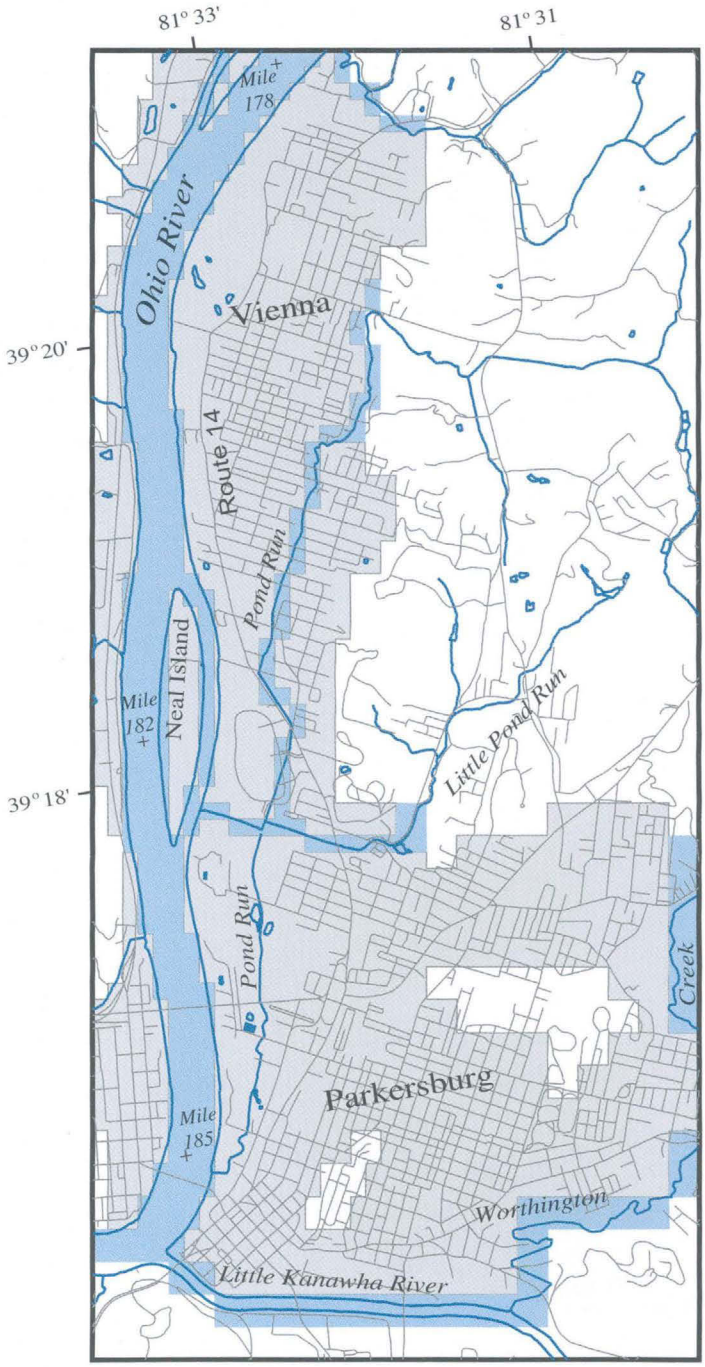

Figure 12. Location of the Parkersburg/Vienna model area, West Virginia (refer to figure 1 for general location map).

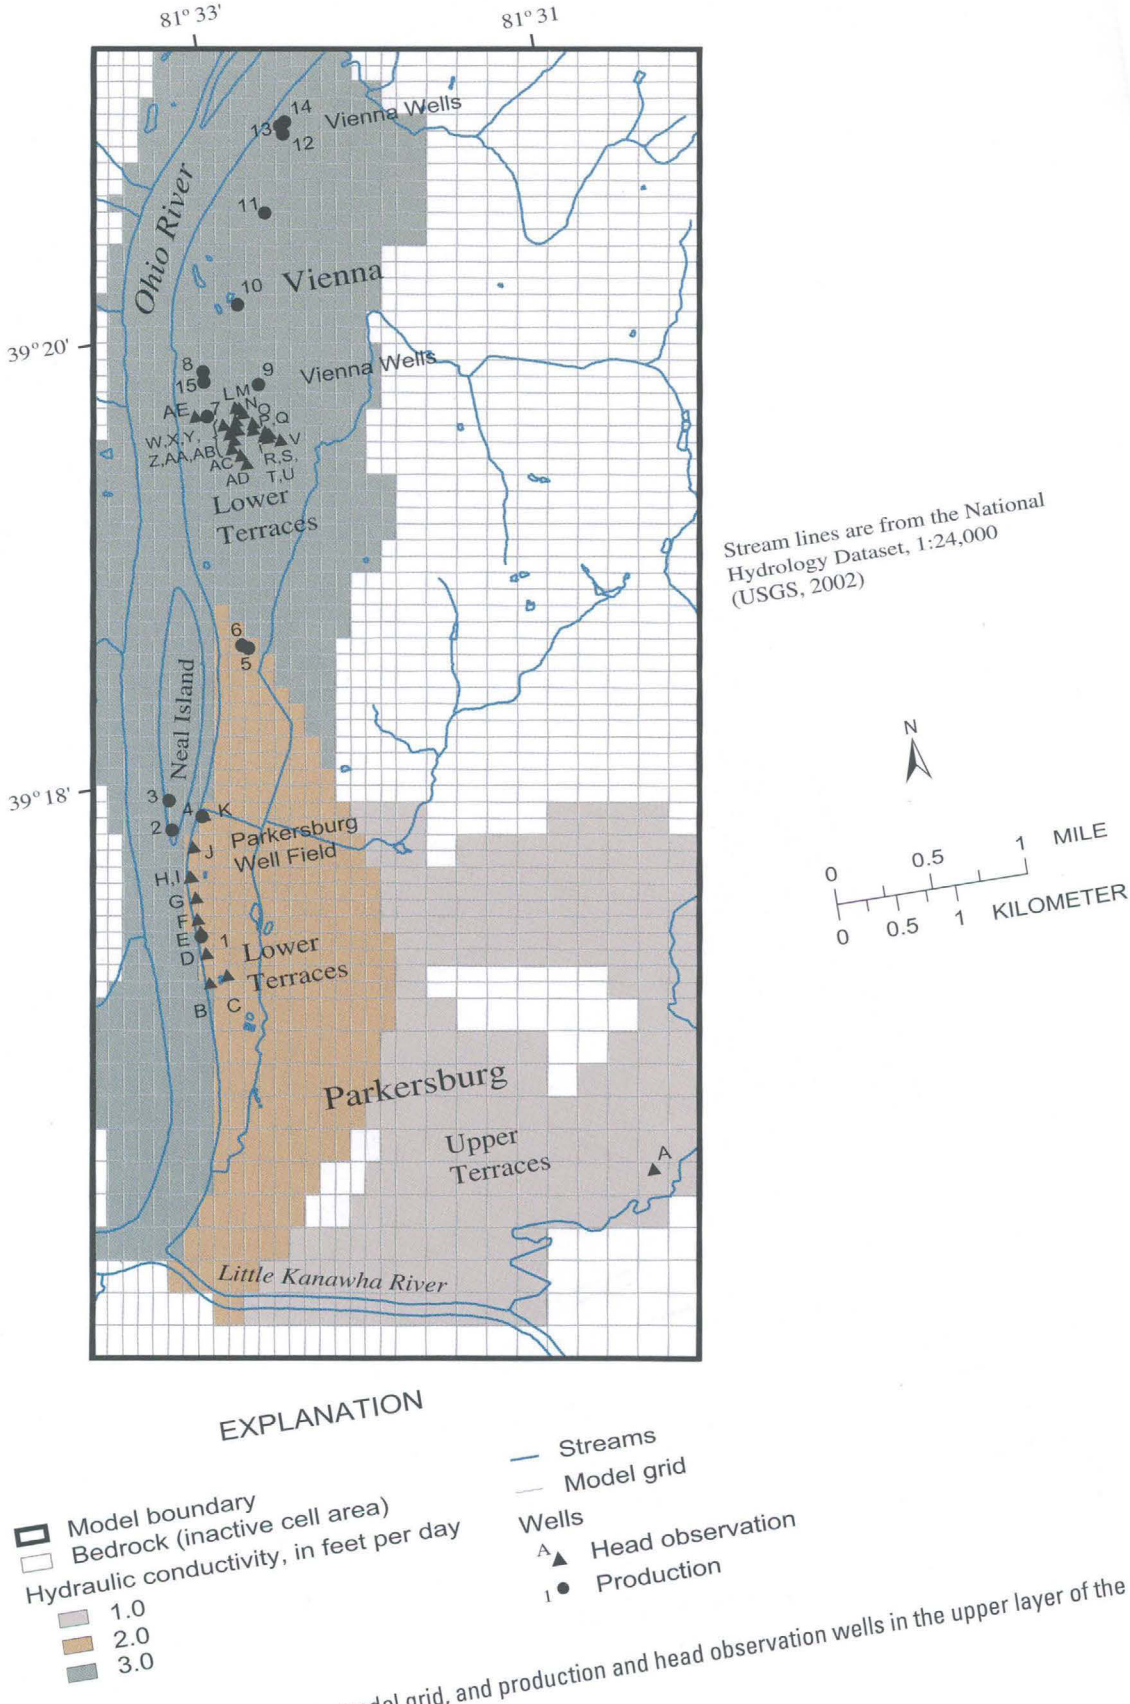

Figure 14. Values of hydraulic conductivity, model grid, and production and head observation wells in the upper layer of the Parkersburg/Vienna model.

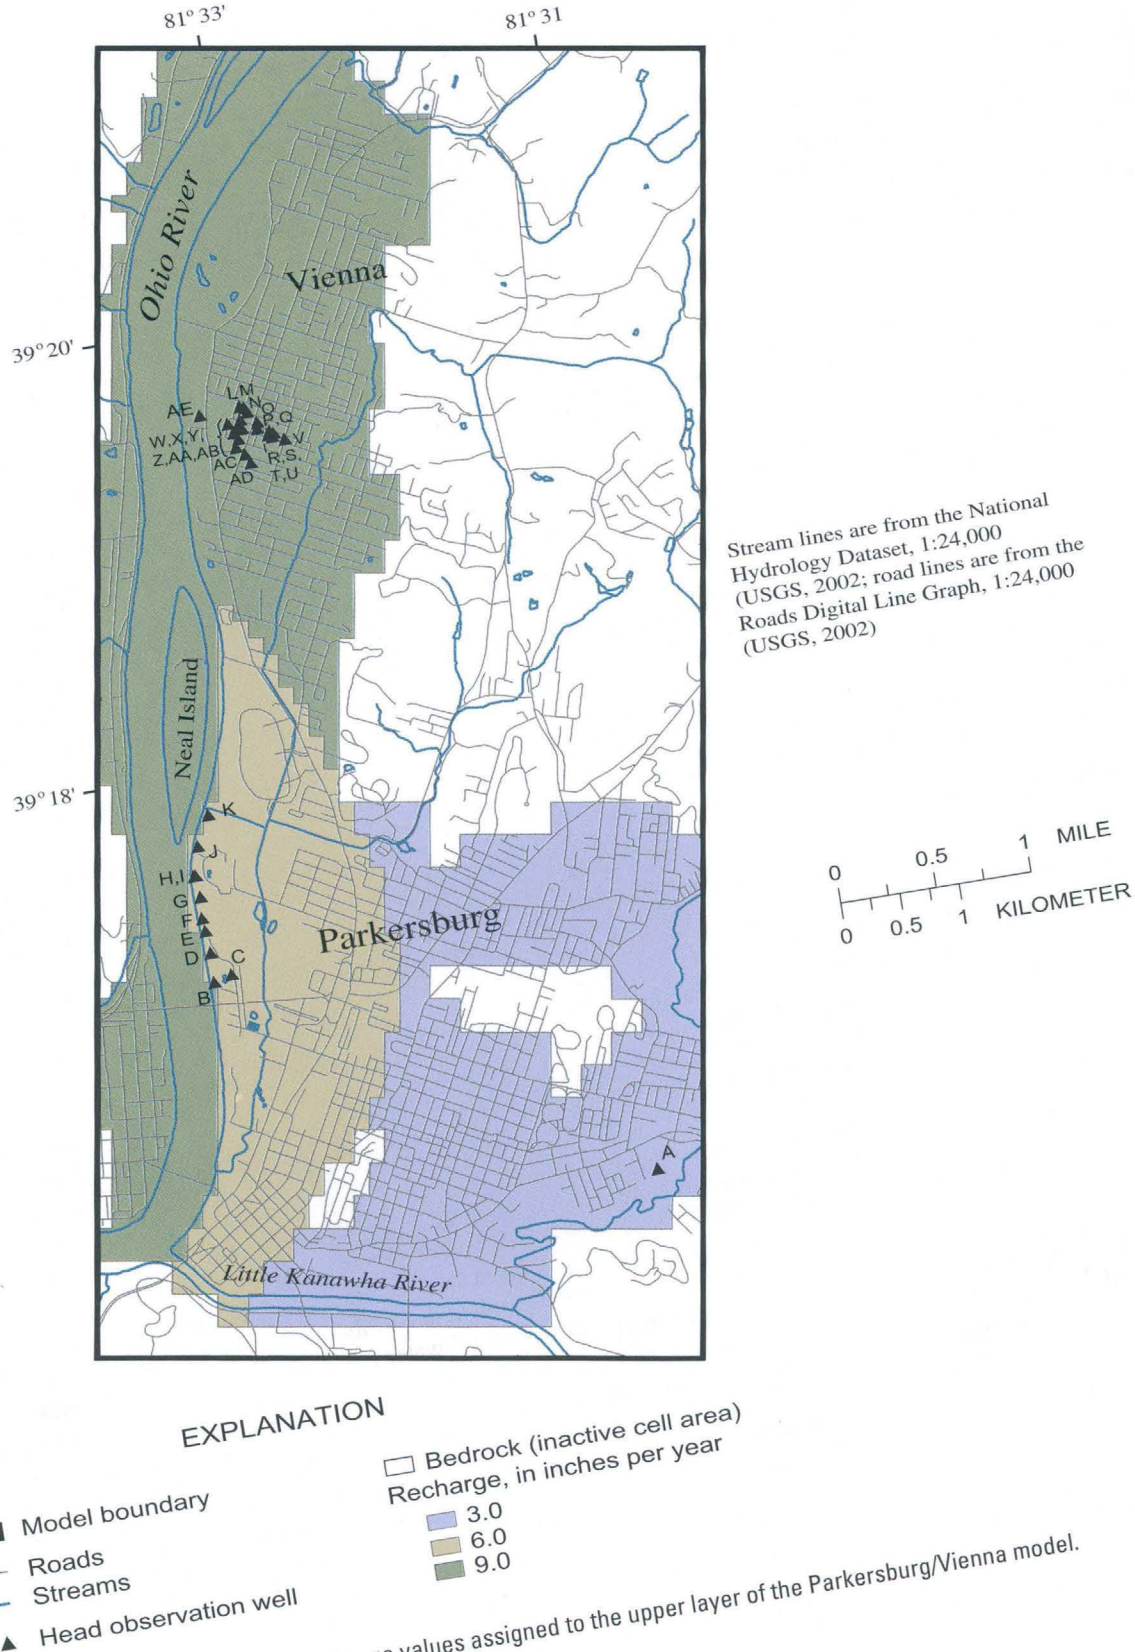

Figure 15. Head observation wells and recharge values assigned to the upper layer of the Parkersburg/Vienna model.

acceptable as water-level data was only collected in the area near the Parkersburg well field as part of this investigation. The remainder of the model, especially for the Vienna area, is based entirely on existing data. Of the wells used for model calibration, only 4 of the 28 wells failed to meet the 4.0 ft error criteria and most simulated water levels calibrated to within a few feet of observed water levels. The calibrated model had a mean error of 1.44 ft and a root mean-squared error of 3.22 ft. Most of the error is from observation wells located near the River or near pumping centers with steep hydraulic gradients. Computed water levels in cells with pumping wells reflect the average water level in the entire cell whereas water levels of observation wells in these cells would be expected to have slightly higher simulated water levels because they generally would not be adjacent to the pumping wells. It is also difficult to match simulated and observed water levels in areas near river cells

The accuracy of the model simulation for the Parkersburg/ Vienna area is mostly related to the characterization of the geometry of the aquifer system. Hydrogeologic data are available for the alluvium at and adjacent to the Ohio River and the Parkersburg and Vienna well fields, but the area closer to the bedrock valley wall has less data and is not as well characterized. The resulting uncertainty of the geometry of the alluvial aquifer could result in errors in time-of-travel estimates made using particle-tracking software. Additional borehole logs would be needed to refine the aquifer geometry in the area near the bedrock valley walls and the uppermost river terraces.

Model Analysis and Interpretation

Ground-water flow in the alluvial aquifer near Parkersburg and Vienna is complicated and has been modified substantially by the cones of depressions from the major pumping wells in the area (fig. 16). This is especially true for the Parkersburg well field (fig. 16) where pumping of 4.78 million gallons of water per day (Mgal/d) has resulted in a cone of depression in the water table approximately 2 mi long parallel to the Ohio River and 1 mi wide.

Conversely, cones of depression around wells in the Vienna area are much smaller (fig. 16) because of two factors. The first factor is total withdrawals: wells in the Vienna area, including the municipal wells and wells at an industrial plant and nearby golf course, only withdraw an average of 1.58 Mgal/d compared to 4.78 Mgal/d for the Parkersburg plant. The second factor relates to well location: wells in the Vienna area are scattered over the entire alluvial flat from the southern end of Vienna to its northern terminus; wells in the Parkersburg well field are clustered in a tight group on the river bank and on Neal Island. There is a considerable difference in hydraulic gradients in the alluvium due to differences in the hydraulic properties of the two areas. The alluvial deposits in the Parkersburg area have a higher percentage of silt and clay than the alluvial deposits in the Vienna area. The confining unit in Parkersburg is substantially thicker than the confining unit in the Vienna area. As a result, withdrawal of ground water in the Parkersburg area produces larger cones of depression than those in the coarser-grained deposits in the Vienna area.

Wells in the Parkersburg well field derive the majority of their water by inducing infiltration from the Ohio River. Collector wells in the well field were designed and built for this purpose. Simulations indicate that approximately 75 percent of water pumped from the Parkersburg well field is derived from the river and only 25 percent is derived from capture of water in the alluvium. Because much of the water in the Parkersburg well field is derived from infiltration of water through the riverbed, estimated 5-year time-of-travel distances for wells are typically short and confined to areas in the riverbed and the area between the cones of depression in the well field itself. The 5-year time-of travel-area is roughly1.18 mi^2 in size.

Wells in the Vienna well field produce less drawdown but typically pull in water over a larger area than wells in the Parkersburg area due to the thinner confining unit in the Vienna area. Typical 5-year time-of-travel areas for wells in the Vienna area are 3,000 ft in diameter or approximately 0.25 mi^2. Ground-water budgets indicate that the Vienna public supply wells receive a much smaller percentage of riverbed recharge than wells in the Parkersburg well field. Of the average 1.4 Mgal/d of water pumped from public supply wells for the city of Vienna, only 7 percent is estimated to be derived from induced infiltration from the Ohio River. The majority (93 percent) is derived by capturing ground water which would have flowed through the alluvium to the river. Smaller private wells, such as wells at a local golf course, a small industrial plant, and a church had much smaller 5-year time-of-travel zones and associated cones of depression.

Moundsville/Glendale

The WVBPH has been mandated to develop WHPA delineations for all public water systems in the State of West Virginia. Many sites for which WHPA delineations are required lack substantive data for model development and calibration. Although there is a sparsity of data, these sites would still benefit from analysis using numerical ground-water-flow models. Successful model development for the Moundsville/Glendale area shows that it is possible to develop models for areas with limited data if there is a good conceptual understanding of ground-water flow in the aquifer. The Moundsville/ Glendale area was selected for model development to represent a worst-case scenario from a modeling standpoint. The Moundsville/ Glendale model was the last of the four models developed in this study so that data and conceptual understanding gained in developing and calibrating the models for the previous three model areas could be extrapolated. This approach resulted in a model, that although limited in calibration data, seems reasonable from a hydrogeologic perspective.

The model for the Moundsville/Glendale area extends from the mouth of Little Grave Creek in the town of Moundsville near Ohio River mile 101.5 north to Glendale Heights near Ohio River mile 98.0 (fig. 17). Of the four models presented in

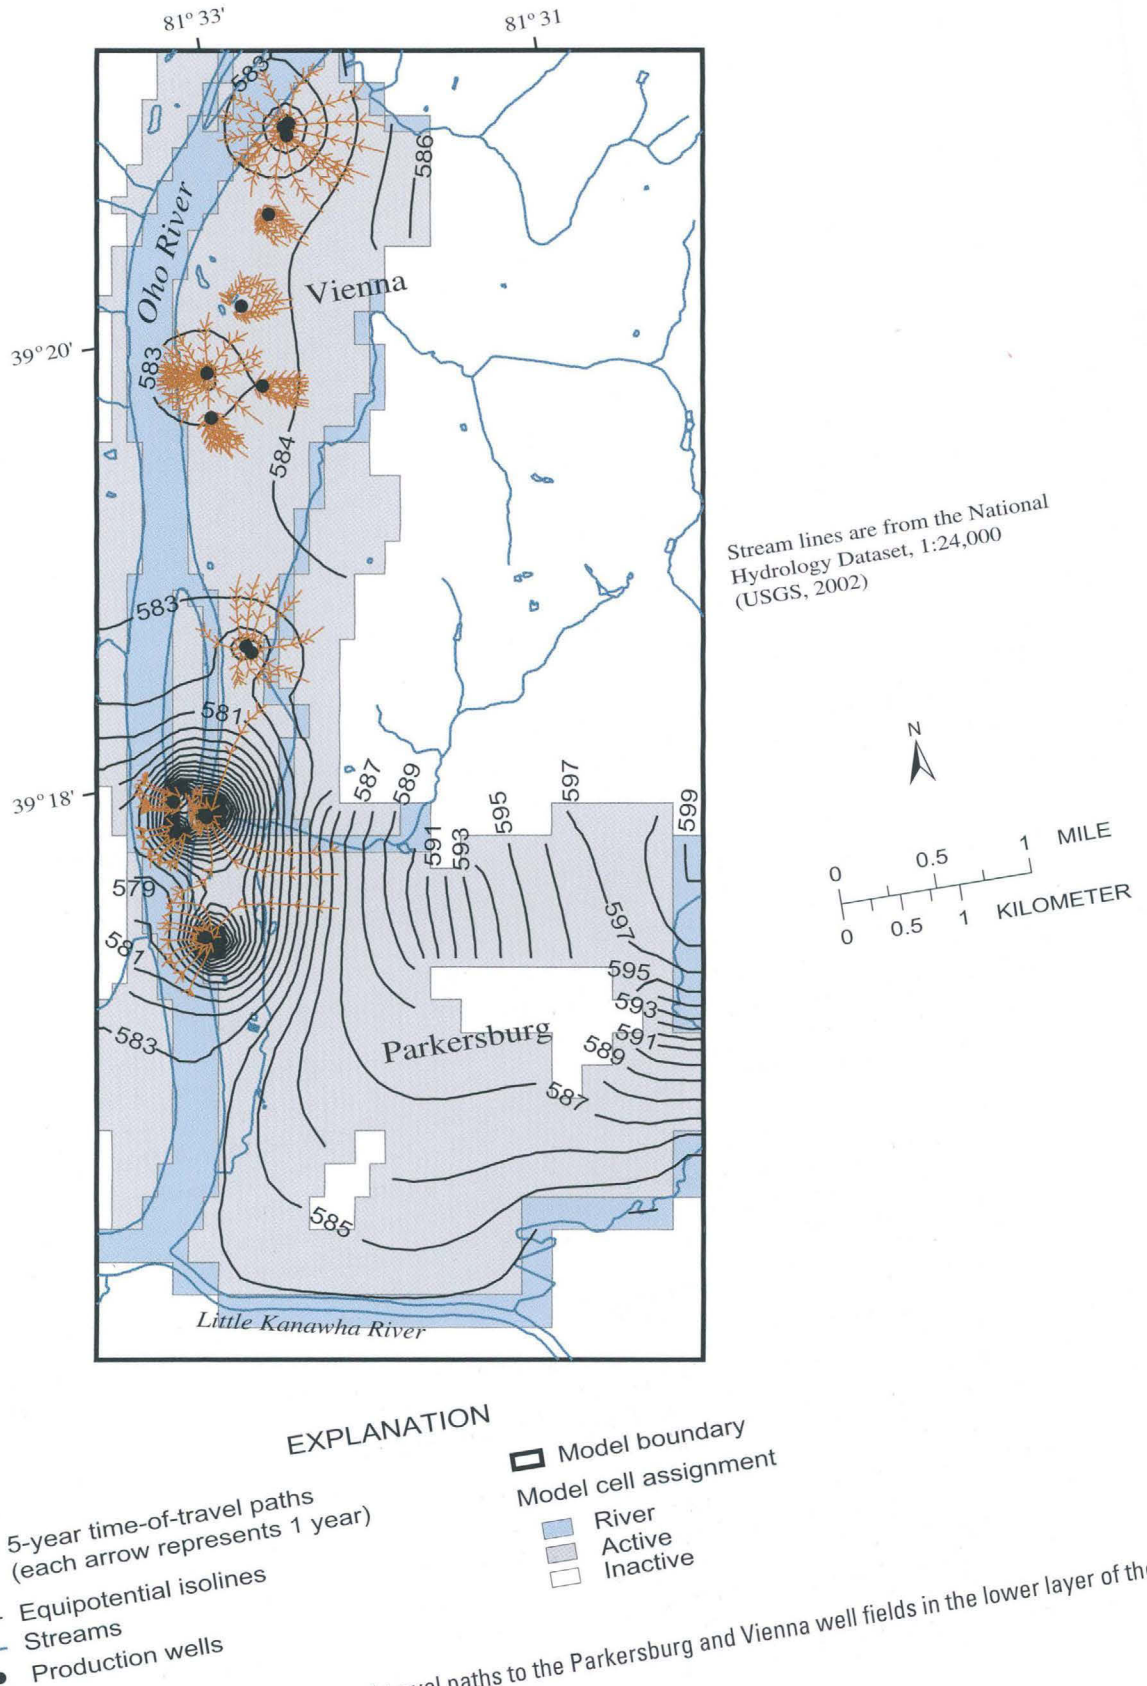

Figure 16. Calibrated heads and 5-year time-of-travel paths to the Parkersburg and Vienna well fields in the lower layer of the model.

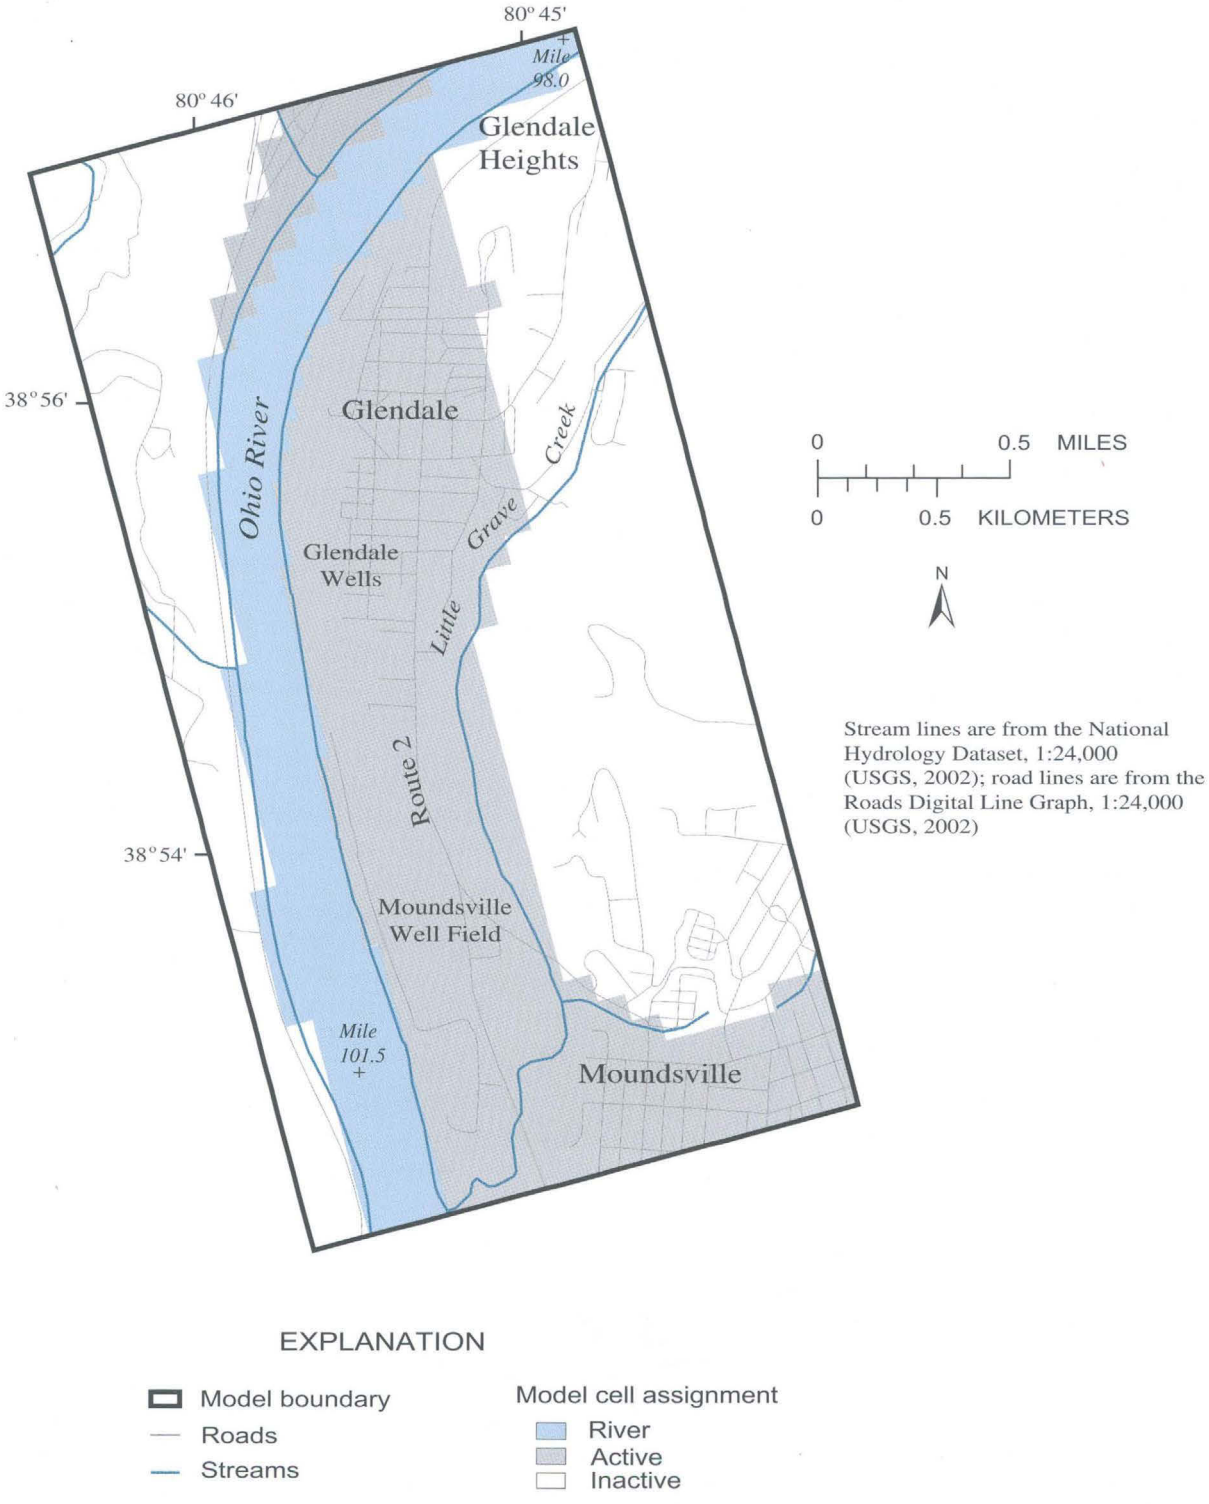

Figure 17. Location of the Moundsville/Glendale model area, West Virginia (refer to figure 1 for general location map).

this report, the Moundsville/Glendale model covers the smallest area. Both the Moundsville and Glendale Water Plants and their respective well fields are close to the Ohio River and are less than 0.25 mi apart. Both well fields combined form a series of wells paralleling the Ohio River over a distance of less than 1 mi. The Moundsville/Glendale model is simplistic from a hydrogeologic standpoint, and is based on simple geometric cross sections representing aquifer geometry with little variation of hydraulic data within the model. The actual geometry and hydraulic characteristics of the aquifer are likely much more complicated.

Data used in the design and calibration of the Moundsville/ Glendale model included written records from archives of the Moundsville (James Woods, Moundsville Water Department, written commun., 2002) and Glendale (Joe Blair, Glendale Water Department, written commun, 2002) Water Plants. Wellhead protection plans prepared by the West Virginia Rural Water Association also provided significant data and insight to conceptualize flow processes in the aquifer for the Moundsville (West Virginia Rural Water Association, 1999a) and Glendale (West Virginia Rural Water Association, 1999b) well fields. In addition, USGS personnel measured water levels in eight nonpumping wells in the Moundsville/Glendale area to assist in model calibration.

Boundary Conditions and Layers

Due to the limited amount of data and the small size of the study area, the Moundsville/ Glendale model is very simple. It consists of only two layers, a lower layer extending from an elevation of 575 to 605 ft representing the lower sand and gravel alluvial aquifer and an upper layer extending from 605 ft to land surface representing an upper silt and clay confining layer. The model consists of 52 rows and 31 columns and contains 1,612 cells (fig. 18). Approximately 40 percent of the cells represent areas with bedrock outcrops and are inactive. The model encompasses an area of 7,766 ft by 15,276 ft, or approximately 4.25 mi^2.

As with the other models, the major boundary conditions for the model are river cells and inactive cells. River cells only were applied to the Ohio River; no tributary streams were simulated in the Glendale/Moundsville area. During the course of this investigation, no flow was evident in any tributary streams in the model area. Unfortunately, the Moundsville/Glendale area was experiencing a severe drought at the time field data were collected for this study; however, even if flow had been present, data collected for the Point Pleasant and Parkersburg/ Vienna models indicate a lack of interaction between tributary streams to the Ohio River and the underlying alluvial aquifer. As with the other models, the seepage of water from adjacent bedrock areas was considered minimal in comparison to flow in the alluvium and infiltration of water from the Ohio River. Therefore, the bedrock areas in the model area were designated as inactive cells.

Hydraulic conductivity data were sparse. A value of 500 ft/d was assigned to the alluvial sand and gravel layer, and a value of 1 ft/d was assigned to the overlying silt and clay confining unit. Estimates of hydraulic conductivity were taken from a statewide report on aquifer characteristics, and data from Marshall County were used to assign values of hydraulic conductivity to the modeled area (Kozar and Mathes, 2001).

Recharge was uniformly applied to the model at a rate of 11 in/yr. This rate is similar to that used in the other models. The relatively thin overlying silt and clay unit and the high permeability of the underlying aquifer results in a slightly higher recharge than in areas dominated by thick silt and clay confining units.

Model Calibration and Limitations

Data available for design and calibration of a ground-water-flow model for the Moundsville/ Glendale area are minimal. Nevertheless, due to the small size of the study area, the water levels that were measured, and the knowledge gained in the design and calibration of the three previous models, ground-water flow in the Moundsville/Glendale area was simulated. The ground-water-flow model for the Moundsville/Glendale area was calibrated by matching simulated and measured water levels. A total of only 8 wells provided water-level data for model calibration. The area is almost exclusively served by public water systems and the 8 wells measured were the only wells available in the study area. Funds were not available for drilling monitoring wells as a part of this investigation and the simulation for the Moundsville/Glendale area was scheduled by design to represent a more or less worst case data scenario for modeling activities in Ohio River alluvium. Due to these limitations, model calibration goals were to match simulated to observed heads within 20% of the overall range in water level within the aquifer (about + or - 2.4 feet). Of the 8 wells used for model calibration, only one had a water level which did not meet the
2.4 ft error criteria. The calibrated model had a mean error of just -0.51 ft and a root mean-squared error of 2.10 ft.

Major limitations of the accuracy of the Moundsville/ Glendale model are primarily related to a lack of data. Additional data including water levels, borehole logs, and aquifer-test data would be needed to better refine the model. Any interpretation of ground-water flow on the basis of this model should be viewed as preliminary and subject to revision given additional data.

Model Analysis and Interpretation

Four principal pumping centers were simulated for the Moundsville/Glendale area. These include the Moundsville and Glendale well fields, an extraction well for ground-water remediation at a local gas station, and the hospital in Glendale. The major pumping center is the Moundsville well field. Pumping from the Moundsville well field produces a large cone of depression around the well field and throughout the surrounding alluvium (fig. 19). Of the approximately 2.0 Mgal/d of water pumped from the Moundsville well field, approximately

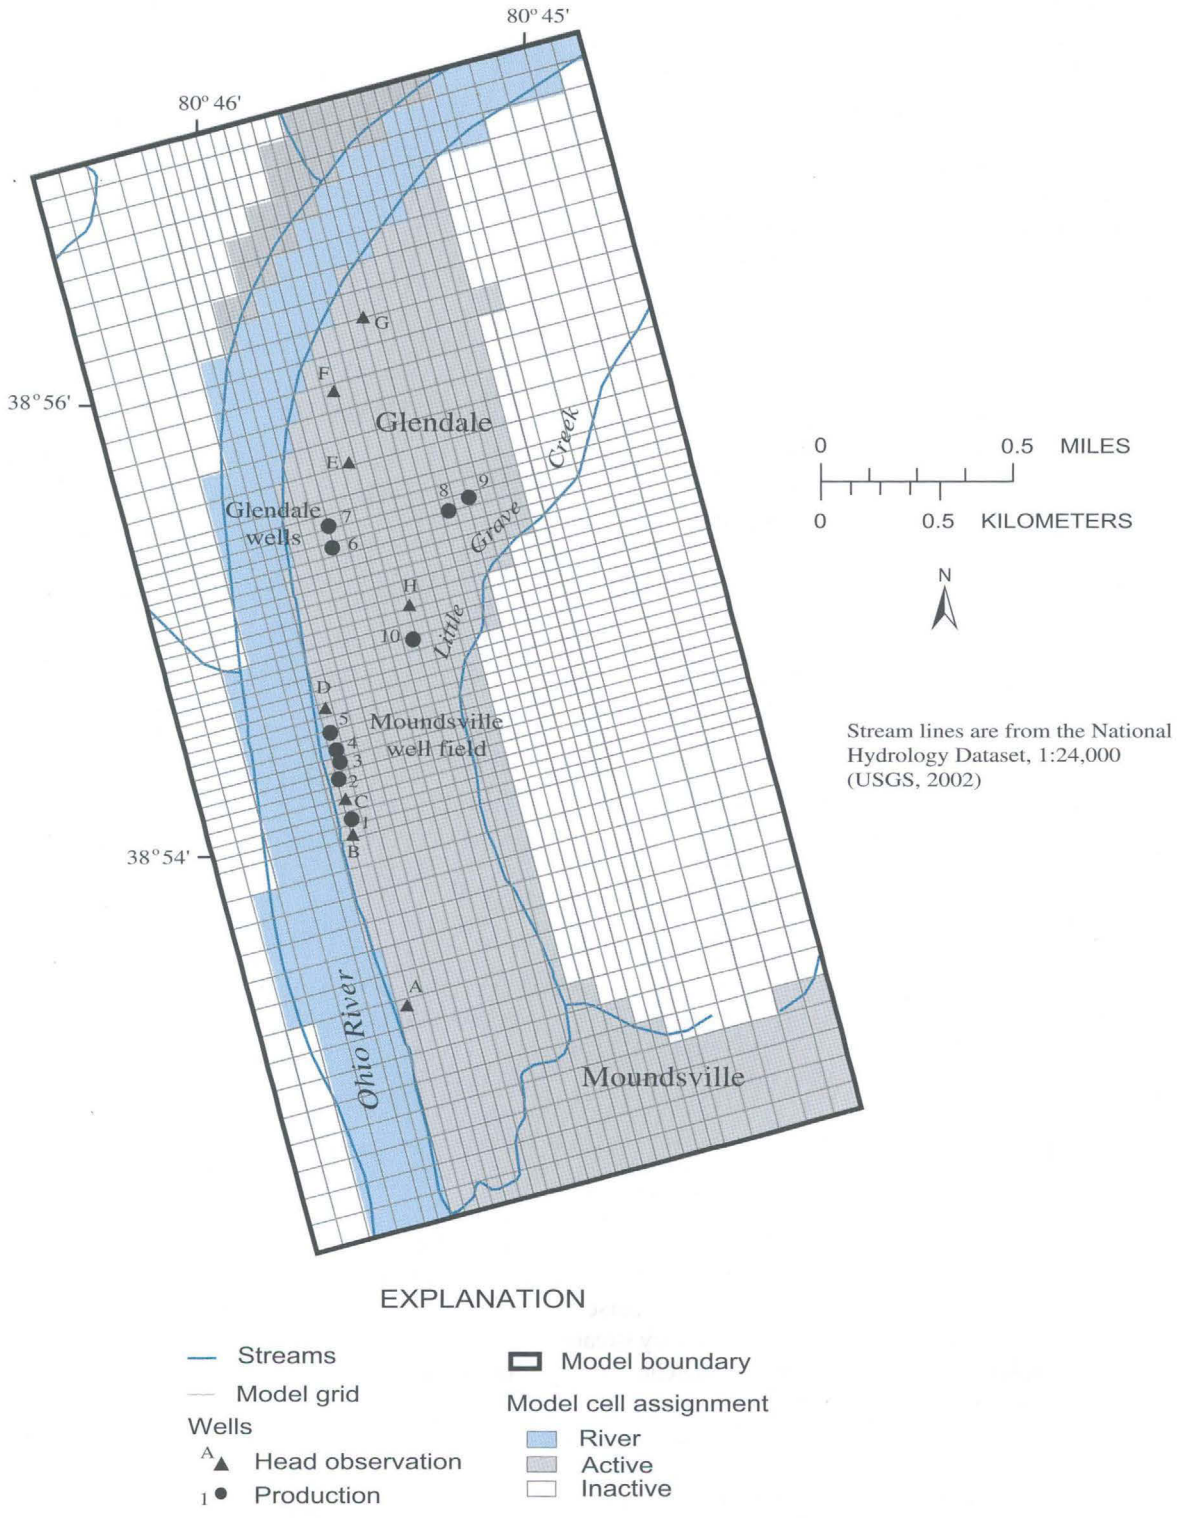

Figure 18. Model grid, locations of production and head observation wells, and inactive cells for the Moundsville/Glendale model.

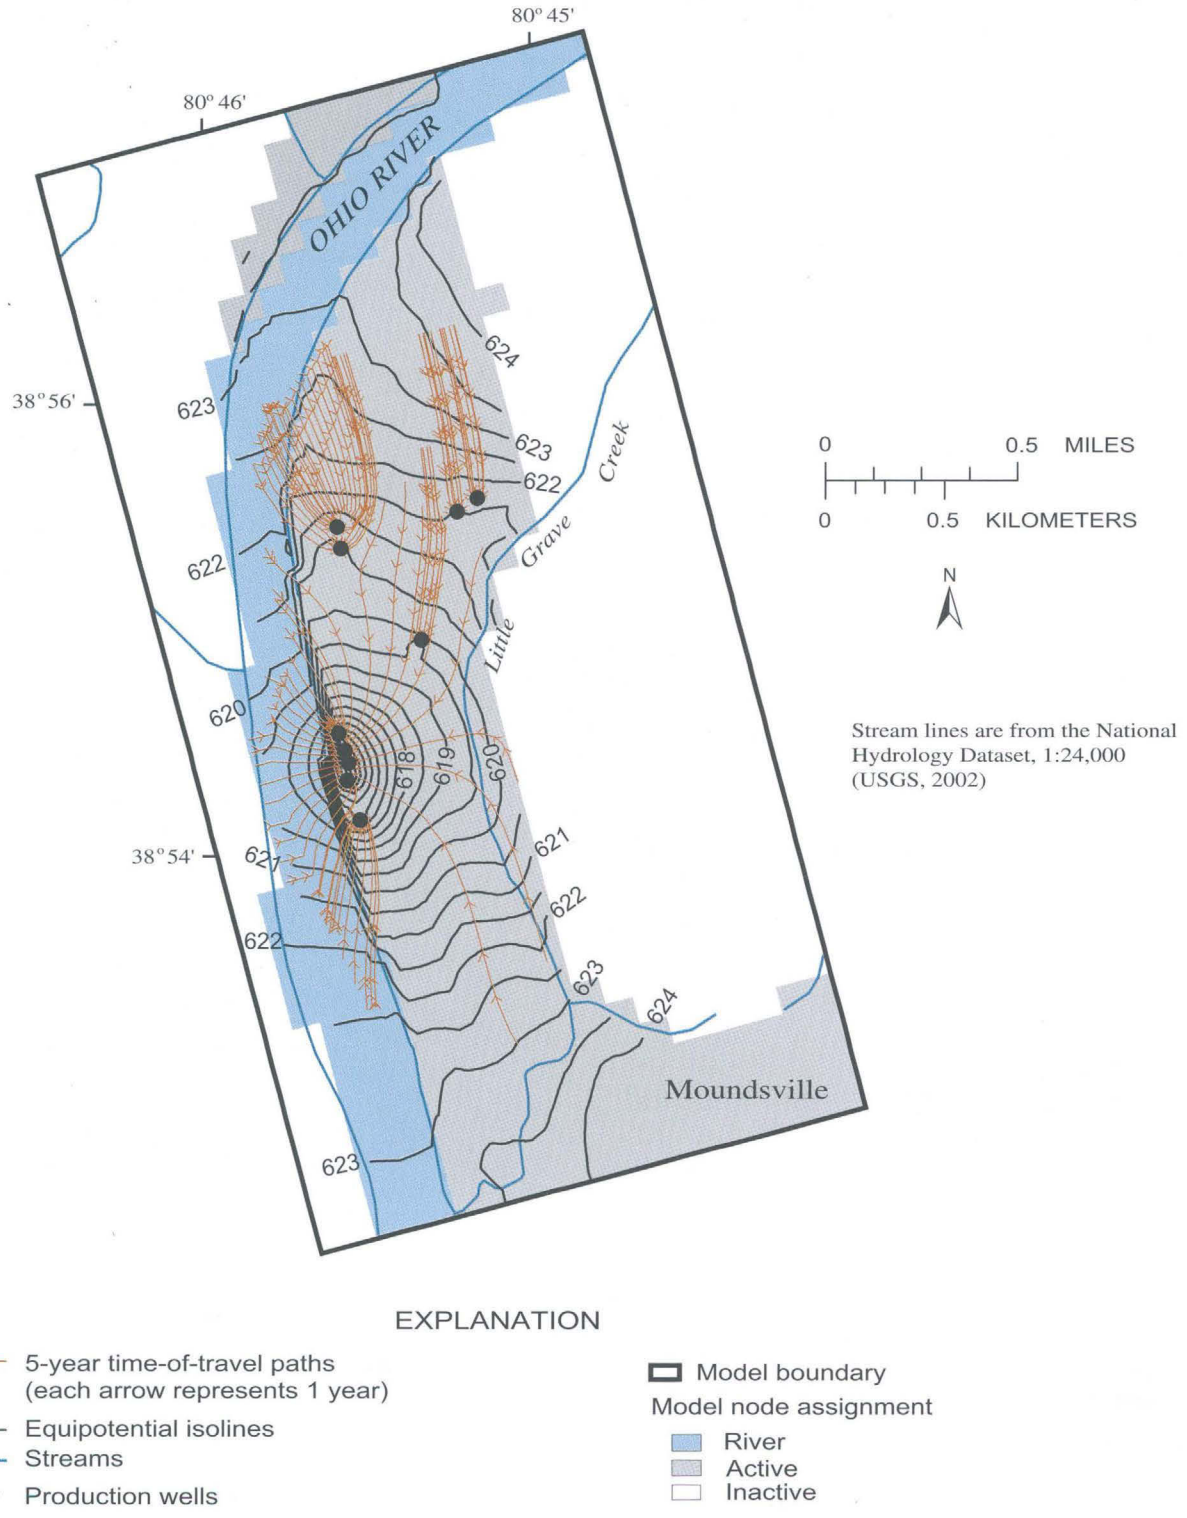

Figure 19. Calibrated heads and 5-year time-of-travel paths to the Moundsville and Glendale well fields in the lower layer of the model.

half is derived from induced infiltration directly from the Ohio River. The remainder is derived from capturing ground water that would have flowed to the Ohio River from alluvium to the north, east, and south of the well field. The 5-year time-of-travel area estimated for the well field covers an elliptical area of approximately 6,750 ft by 3,250 ft, or approximately 0.79 mi^2.

The second major pumping center is the Glendale well field. The majority of water flowing (72 percent) to the Glendale well field is induced infiltration of water from the Ohio River. A smaller percentage of flow (28 percent) is derived by capturing water from the alluvial terraces north of the well field. The 5-year time-of-travel area is small, approximately 2,750 ft by 1,150 ft, or 0.11 mi^2 (fig. 19). Two other minor pumping centers, a local gas station and a hospital, receive 100 percent of flow from the alluvium with no induced infiltration from the Ohio River. The primary recharge area for these two minor withdrawals is primarily to the north of the wells.

Sensitivity Analysis

Ground-water-flow models described in this report were designed and calibrated based on various parameters: boundary conditions, recharge, layer configurations, and hydraulic conductivity. Because boundary conditions and layer configurations were established from site-specific data and well logs, there was little opportunity to vary these parameters. Only recharge and hydraulic conductivity values could be varied in each model for calibration purposes. Sufficient data were available to develop good preliminary estimates of hydraulic conductivity and recharge. Significant variability in recharge and hydraulic conductivity resulted from variations in the composition of the alluvial sediments in each modeled area. This was especially true for the upper silt and clay confining layers for which little data were available. As a result, parameters were varied during the calibration phase to provide a best fit between observed and calculated hydraulic heads and hydrologic budgets. Parameters were also varied to determine how "sensitive" the models were to variations in input parameters.

The ranges of hydraulic conductivity and recharge rates for the various models and the effect varying these parameters had on the calibration error for the models (root mean squared and mean error) are listed in table 4. The effects of varying the parameters arepronounced in some instances and negligible in others. Overall, the models are more sensitive to variations in recharge than they are to variations in hydraulic conductivity. The models also are sensitive to the hydraulic conductivity of confining units when hydraulic conductivities are small. An example is the Washington Bottom and Moundsville upper terraces (table 4) where small changes in hydraulic conductivity have rather pronounced effects on simulated heads. As a result, known values of hydraulic conductivity were used to calibrate the models where possible. The major data limitation indicated by sensitivity analysis is information on hydraulic properties of the confining units.

Summary

Ground-water-flow simulations were developed for alluvial aquifers bordering the Ohio River in Point Pleasant, Lubeck/Washington Bottom, Parkersburg/ Vienna, and Moundsville/Glendale, West Virginia. The models were developed to assess ground-water-flow rates and directions in alluvial aquifers and to assess the effects of large ground-water withdrawals on the ground-water flow system. This study was initiated in 2000 and was done in cooperation with the West Virginia Bureau for Public Health (WVBPH). The models can be used by water-resources managers to develop source-water protection areas for public supply wells in the study areas and in other Ohio River alluvial aquifers. Five-year time-of-travel zones, identified by use of particle tracking, were included as part of this investigation.

The geology of the areas for which ground-water models were prepared is typified by highly permeable sand and gravel glacial outwash deposits overlying bedrock. The hilly terrain of south-southeast dipping Lower Permian and Pennsylvanian age rocks is dominant in the upland areas and gives way to a flood plain less than 500 feet (ft) below. Pleistocene alluvium from glacial outwash deposits of the pre-, early-, and late-Wisconsinan age has been reworked and deposited at lower elevations, forming terraces. The alluvial deposits have the capacity to yield millions of gallons of water per day to wells, especially wells completed in river-bank deposits or completed as long horizontal lateral collector wells extending beneath the river. Fluvially deposited layers of silt and clay typically cover the

glacial outwash deposits, forming a thin overlying confining unit that limits recharge from precipitation. The confining unit is present in all modeled areas but is partially absent in the Point Pleasant area. The alluvium there, from the river bank to about 1 mile (mi) east of the river is typified by more permeable sands and to a lesser extent gravels at the base. An old meander cutoff (oxbow) in the Point Pleasant area is characterized by a confining layer of silt and clay between upper and lower alluvial aquifers.

Under base-flow conditions, hydraulic gradients typically indicate ground-water flow from the alluvium towards the river. Infiltration from the river can occur naturally when local hydraulic gradients are reversed during high river stages that are common during floods. Induced infiltration from the Ohio River is likely where the aquifer is pumped close to the river, although local heterogeneity of river bottom sediments may reduce the connection (Mathes and others, 1995; Jeffords, 1945).

No appreciable gains or losses in streamflow were detected in any of the areas and tributary streams are therefore believed to have little connection with the underlying alluvial aquifer. Discharge from surrounding bedrock aquifers serves as an additional source of ground water but is likely small in comparison to that derived from precipitation. In the absence of significant recharge from tributary streams and from bedrock, the majority of recharge under ambient conditions is from precipitation. A large part of precipitation is lost to surface runoff and evapotranspiration. Estimates of ground-water recharge for alluvial aquifers bordering the Ohio River range from 3 to 20 in/yr. Estimates of ground-water recharge applied to models in this report range from 3 to 12 (in/yr) and vary based on the composition of the alluvium. Alluvial deposits with a high percentage of sand and gravel tend to have recharge rates approaching 12 in/yr whereas the deposits with a high percentage of silt and clay (thicker and more areally extensive confining units) may have recharge rates as low as 3 in/yr.

In the study area, the alluvium varied in thickness from 45 to 100 ft. The thickness in the Point Pleasant well field was (75-95 ft), Lubeck (60-85 ft), Parkersburg (45-65 ft), Vienna (70 to 80 ft), and Moundsville/Glendale (65 to 100 ft). The average hydraulic conductivity of the alluvium in each well field was Point Pleasant (350 ft/d)), Lubeck (190 ft/d), Parkersburg (175 ft/d), Vienna (300 ft/d), Moundsville (500 ft/d), and Glendale (500 ft/d). The depth to water in the alluvium varied from 24 to 58 ft below land surface.

Because glacial outwash deposits in alluvial flats in the northern part of the study area consist of coarser grained sediments than the alluvial flats further to the south, the hydraulic conductivity of the alluvial flats to the north (300 to 500 ft/d) are typically higher than those to the south (75 to 300 ft/d). Fine-grained flood plain sediments of fluvially deposited silt and clay cover the coarser grained glacial outwash deposits but typically have very low hydraulic conductivities of 0.1 to 3.0 ft/d.

Public-supply wells in alluvial sediments along the Ohio River have the capacity to yield extremely large quantities of water. For public supplies described in this report, Parkersburg withdraws the most water at 4.78 million gallons per day (Mgal/d) and the Camp Conley Public Service District withdraws the least at only 34,000 gallons per day (gal/d). Average ground-water withdrawals for the remaining well fields are: Point Pleasant (1.09 Mgal/d), Lubeck (0.67 Mgal/d), Vienna (1.40 Mgal/d), Moundsville (2.36 Mgal/d), and Glendale (0.26 Mgal/d). Two large chemical manufacturing facilities in the area immediately north of the Lubeck well field withdraw approximately 8.80 Mgal/d and 2.06 Mgal/d, respectively. Such large withdrawals are common for industrial and public-supply wells along the Ohio River.

Results of the simulations conducted for the Point Pleasant area indicate that only a minimal amount of the water (approximately 4 percent) that is pumped from the Point Pleasant well field is derived from induced infiltration from the Ohio River. The majority of water (96 percent) is derived from a large capture zone, approximately 5,000 ft by 4,700 ft, that surrounds the Point Pleasant well field. The 5-year time-of-travel area occupies approximately 0.84 mi^2. The contaminated land to the south of the plant is within the cone of depression of the nearby Point Pleasant well field. Water from the adjacent contaminated site could potentially migrate to the Point Pleasant well field, depending on pumping scenarios in the well field. For the Camp Conley Public Service District, none of the water pumped originates from the Ohio River. The 5-year time-of-travel area for the Camp Conley well field is small, less than 0.25 mi long, and derives most of its water from a small area primarily to the east of the well field. It is not likely to be affected by the contaminated sites adjacent to the Point Pleasant well field but could be vulnerable to contamination from other potential sources of contaminants in the area.

In the Lubeck well field, ground-water flow simulations show that ground water is derived from the area immediately adjacent to the well field near Vaughts Run and Sandy Creek. Part of the flow also is derived directly from the Ohio River. Hydraulic gradients indicate that the water table near the Lubeck well field is actually at a higher elevation than the water table near the chemical manufacturing facilities in the Washington Bottom area. It does not appear likely that the Lubeck well field captures flow from the northern part of the Washington Bottom area. Of the approximately 665,000 gal of water pumped daily from the Lubeck well field, approximately 261,600 gal (39 percent) is derived from induced infiltration from the Ohio River and approximately 403,400 gal (61 percent) is derived from ground water in the alluvium that would otherwise have flowed to the Ohio River.

Ground-water flow in the alluvial aquifer near Parkersburg and Vienna is complicated and has been modified substantially by the cones of depressions formed from the major ground-water withdrawals in the area. This is especially true for the Parkersburg well field where pumping of 4.78 Mgal/d has resulted in a cone of depression approximately 2 mi long parallel to the Ohio River and approximately 1 mi wide. Conversely, cones of depression around wells in the Vienna area are much smaller. This is due to a difference in total withdrawals and in well spacing. Wells in the Vienna area, including the municipal

wells and wells at an industrial plant and nearby golf course, withdraw a total of 1.58 Mgal/d compared to 4.78 Mgal/d for the Parkersburg plant. The wells in the Vienna area are scattered over the entire alluvial flat from the southern end of Vienna to its northern terminus, whereas wells in the Parkersburg well field are clustered in a tight group on the river bank and on Neal Island. In addition, the deposits in the Parkersburg area have a higher percentage of silt and clay than do alluvial deposits in the Vienna area, and the confining unit in Parkersburg is substantially thicker than the confining unit in the Vienna area. As a result, withdrawal of ground water in the Parkersburg area produces larger cones of depression than would occur in the coarser grained deposits in the Vienna area. Approximately 75 percent of the water pumped from the Parkersburg well field is derived from infiltration of water from the Ohio River whereas only 7 percent of water pumped from the Vienna well field is derived from the Ohio River.

In the Moundsville/Glendale area, pumping from the Moundsville well field produces a large cone of depression around the well field and throughout the alluvium. Of the approximately 2.0 Mgal/d pumped from the Moundsville well field, approximately half is direct infiltration of water from the Ohio River. The remainder is derived from capturing ground water in the alluvium that would have flowed to the Ohio River from the area south of the well field. The majority of recharge (72 percent) to the Glendale well field is direct infiltration of water from the Ohio River. A smaller proportion (28 percent) of recharge is derived from precipitation falling on the alluvium. Pumping from the Glendale well field does not produce a cone of depression but rather a small 5-year time-of-travel area of approximately 0.11 mi^2.

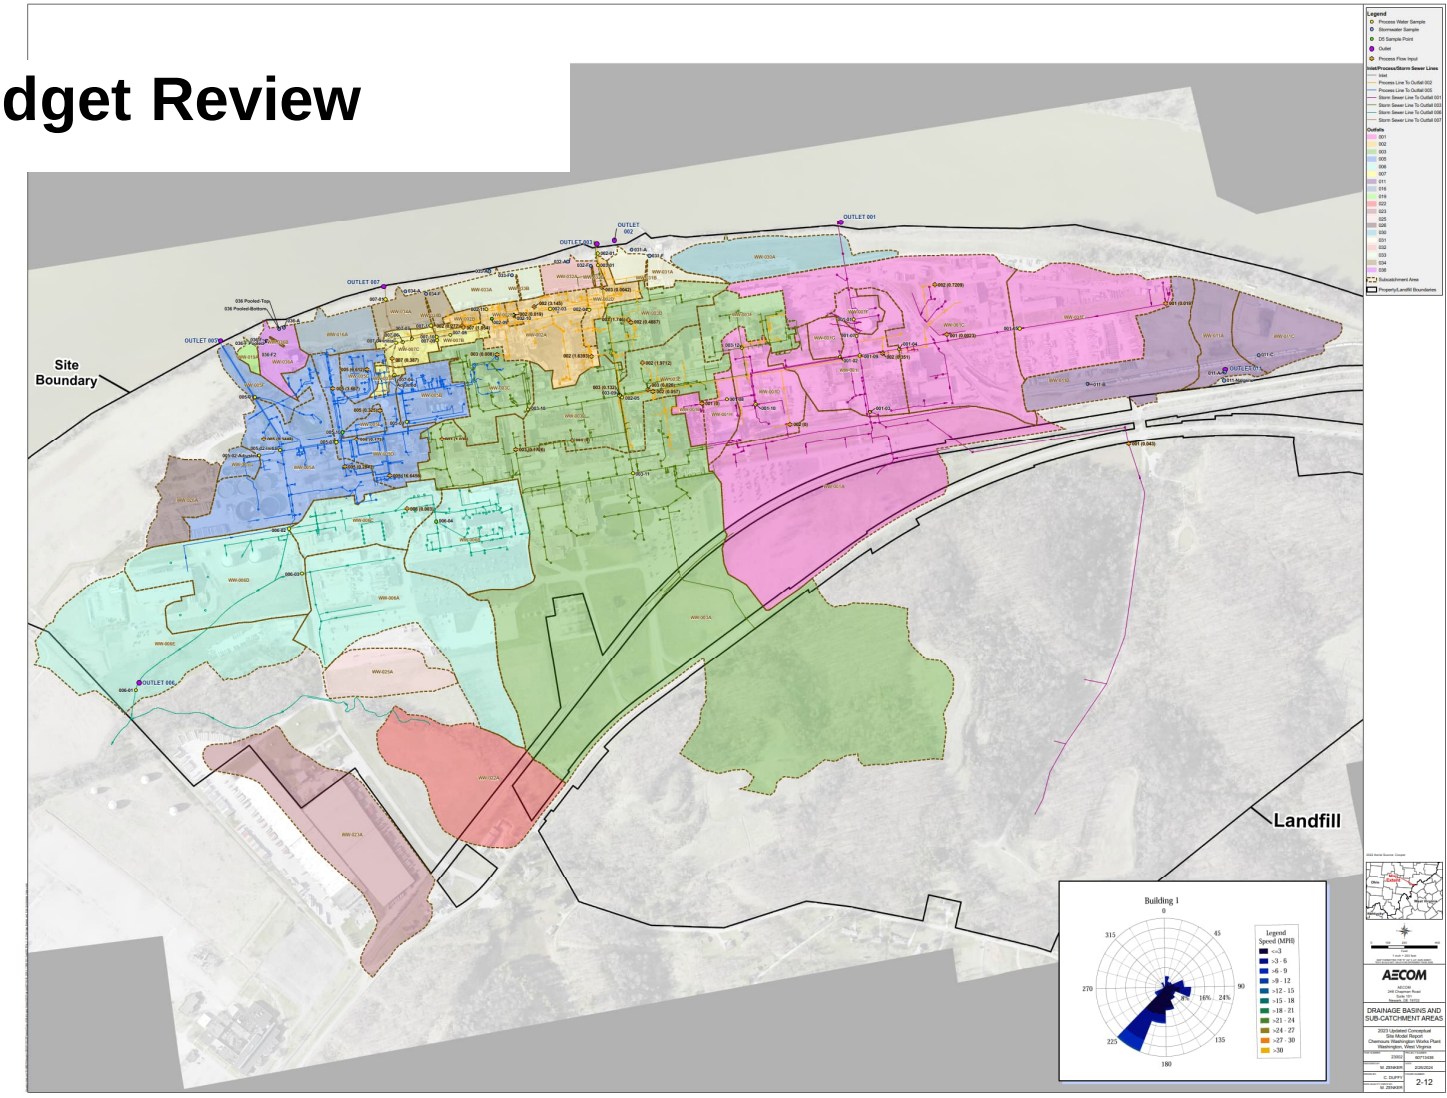
Preliminary Water Balance Estimate

Preliminary Water Budget Review

- Estimated Water Balance
  - Order of magnitude estimate
  - Sources/Sinks
- Hydraulic Containment



Estimated Water Budget – Sources and Sinks of Water to the Site

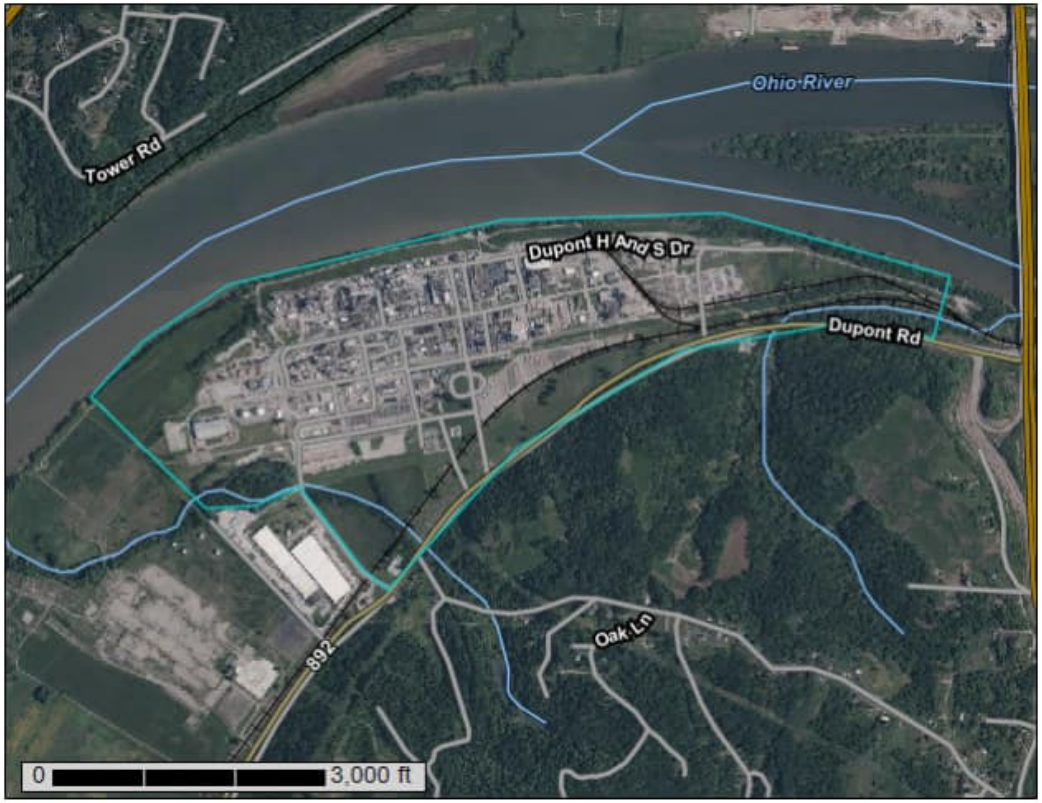
- **Sources**
  - **Precipitation** (highly variable rate)
  - **Infiltration** to the alluvial aquifer under the site **from Ohio River** (steady rate caused by gradient induced by the process water wells)
  - Groundwater flow from bedrock south of site (believed to be minor)
- **Sinks**
  - **Evapotranspiration** (seasonally active in vegetated areas)
  - **Runoff** (highly variable rate occurring when precipitation exceeds infiltration to soil)
  - **Discharge** of water from site to the Ohio River **from** process **outfalls**
- **Transfer processes** on site
  - Removal from alluvial aquifer by **process wells** (steady rate depending on process needs)
  - **Runoff** from paved areas to ditches (during precipitation events)
  - **Infiltration** to aquifer (in unpaved areas when soil field capacity exceeded)
- **Simplifying Assumptions:**
  - Annual timescale – ignores transient events that do not reflect long-term
  - Bulk estimate based on: groundwater extraction rates, land use, available precipitation and soil data

Climate Assumptions - Precipitation

Site extent within the cyan polygon at right is 414.5 acres.

Precipitation estimated from the USDA soil survey is 34 to 48 inches per year.

This equals **1,174 to 1,658 acre-feet of rainfall per year.**



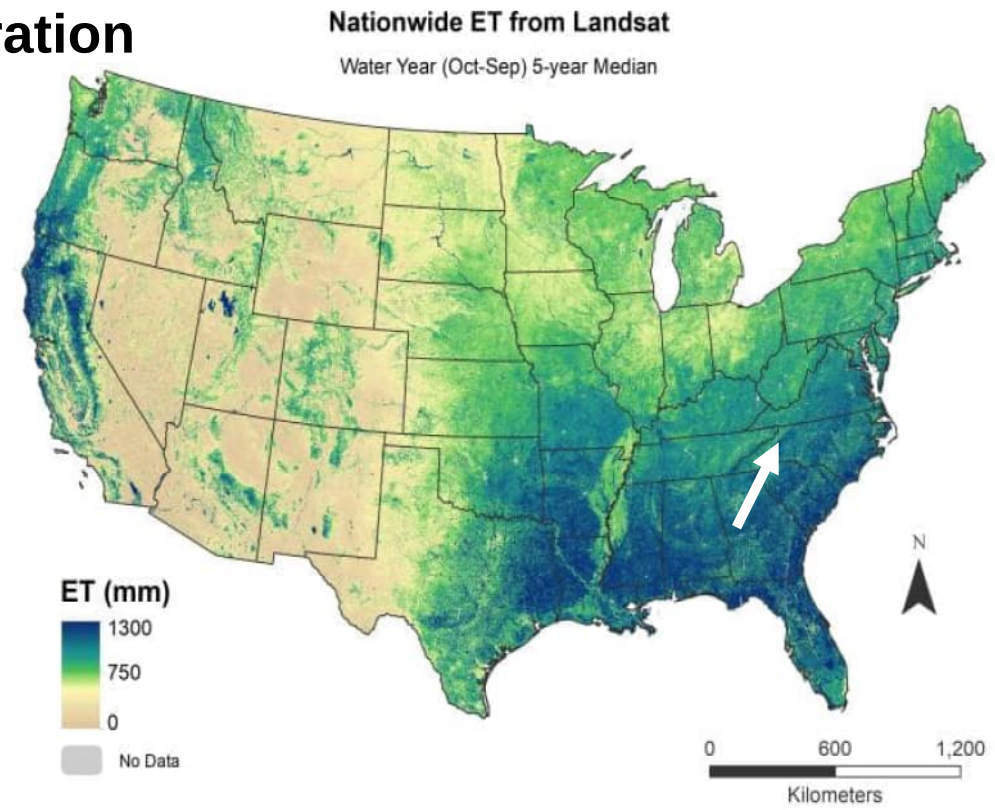
Soil map from the USDA (shown in a later slide) for the 414.5 acres shows that essentially half of the surface (209.5 acres) is “Ma” (“made land” i.e., developed).

Two-thirds of the “made land” is impermeable and graded to drain.

Climate Assumptions – Evapotranspiration

- **Evapotranspiration** is most active in summer months (and very limited in winter).
- Actual evapotranspiration data are not available for the site.
- Based on map at right, estimate about 750 mm per year (75 cm or 29.5 inches) for vegetated areas.
- For this estimate, assume Evt is fully active on vegetated soils. Assume 50% Evt on unpaved "made land" (i.e., gravel).

(https://eros.usgs.gov/doi-remote-sensing-activities/2022/usgs/landsat-actual-evapotranspiration-model-advancements-nationwide-water-use-mapping)



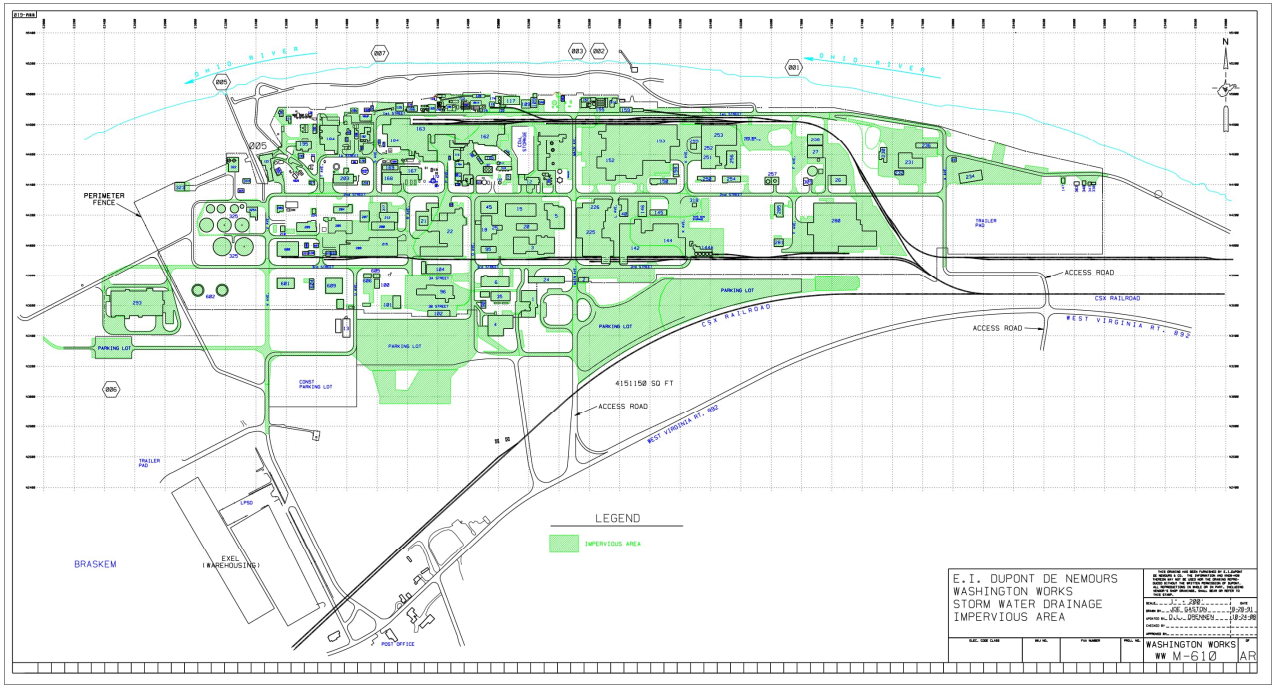
Annual Total Water-Year SSEBop Actual Evapotranspiration using 5-year median (2009, 2011, 2013, 2016, 2018) data from Landsat. No Data values represent isolated areas with missing model auxiliary input data. The associated manuscript is available here (https://doi.org/10.1016/j.rse.2022.113011).

Site Surface Conditions – Impervious Areas

Of the site area that is “made land”, roughly 2/3^{rds} (209.5 * 2/3 = 139.4 acres) is paved or otherwise impervious.

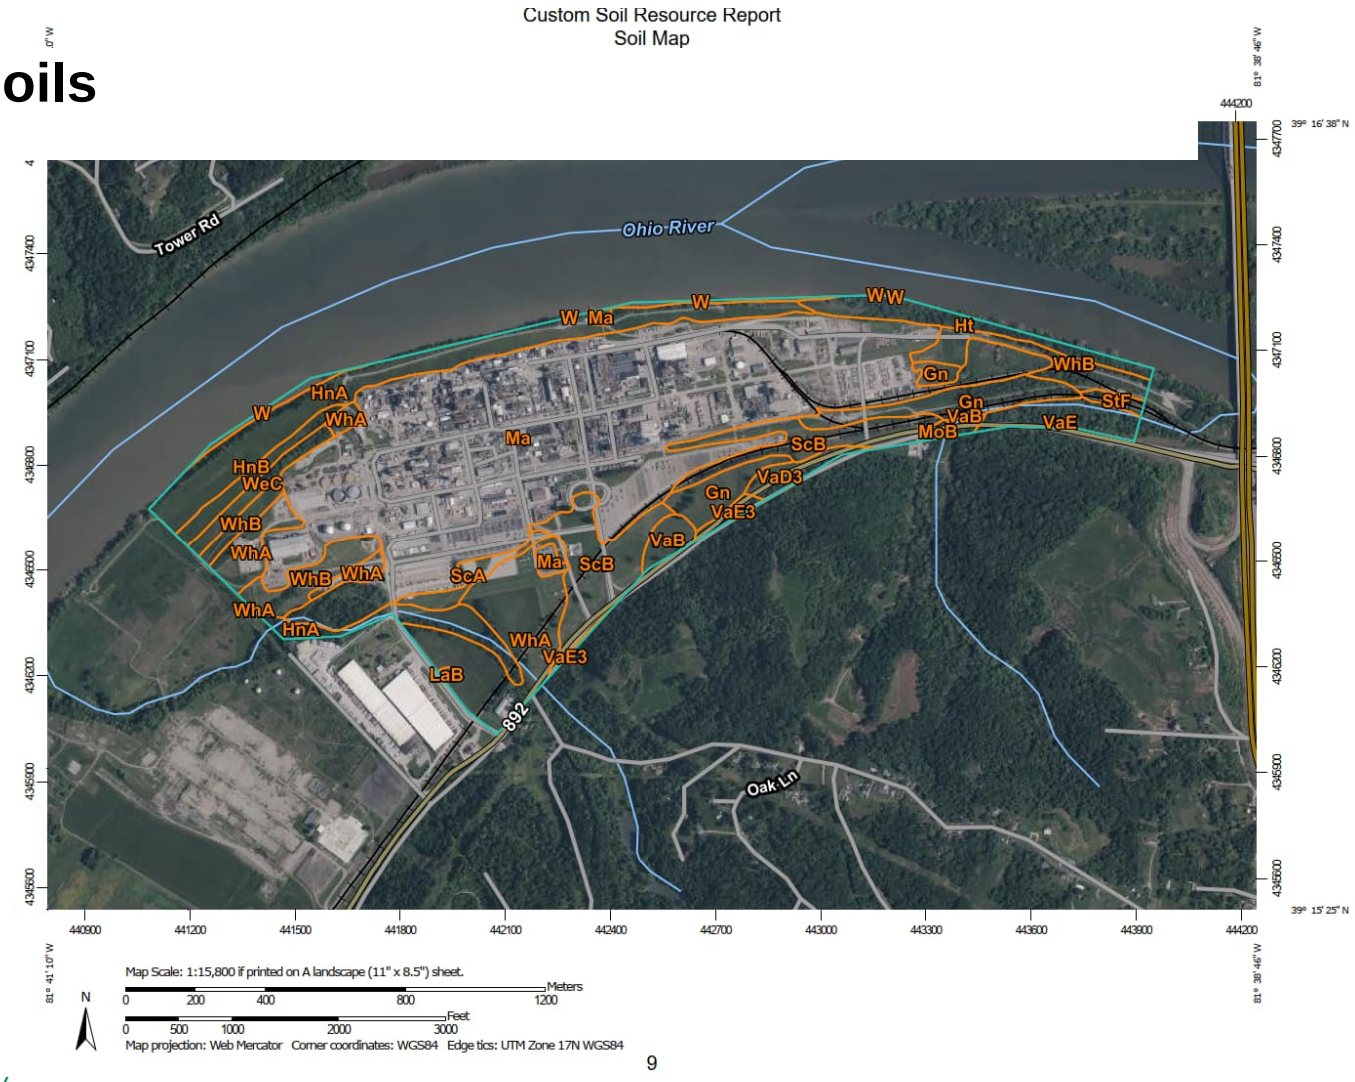
All precipitation landing on paved areas is assumed to runoff via site ditches (no infiltration or evapotranspiration).

The other “made land” is developed in some way and is assumed to have limited vegetation (assume 50% of evapotranspiration)



Site Surface Conditions - Soils

- Infiltration to the aquifer occurs when precipitation exceeds the field capacity of the soil.
- With moderately high to high infiltration rates for vegetated soil of the site, expect that this volume is significant.
- Areas disturbed by development have reduced infiltration



9

Custom soil map from the USDA's Web Soil Survey. https://websoilsurvey.nrcs.usda.gov/app/

Site Surface Conditions – Soil Types and Infiltration Potential

- After “made land”, most of the soil units in the facility are vegetated silt-loams with **moderately high to high infiltration rates**.
- Infiltration was estimated in the groundwater model (next slide)

Map Unit	Symbol Map Unit Name	Acres in AOI	Percent of AOI		Capacity of the most limiting layer to transmit water (Ksat):
Gn	Ginat silt loam	20	4.83%		Very low to moderately low (0.00 to 0.06 in/hr)
HnA	Huntington silt loam, 0 to 3 percent slopes	42.9	10.35%		Moderately high to high (0.57 to 1.98 in/hr)
HnB	Huntington silt loam, 3 to 10 percent slopes	5.4	1.30%		Moderately high to high (0.57 to 1.98 in/hr)
Ht	Huntington silt loam, low bottom	13.4	3.23%		Moderately high to high (0.57 to 1.98 in/hr)
LaB	Lakin loamy sand, 3 to 10 percent slopes	0.3	0.07%		High to very high (5.95 to 19.98 in/hr)
Ma	Made land	209.5	50.54%		Undetermined
MoB	Moshannon silt loam, 3 to 10 percent slopes	0.7	0.17%		Moderately high to high (0.57 to 1.98 in/hr)
ScA	Sciotoville silt loam, 0 to 3 percent slopes	4.3	1.04%		Moderately low to moderately high (0.06 to 0.57 in/hr)
ScB	Sciotoville silt loam, 3 to 10 percent slopes	31.3	7.55%		Moderately low to moderately high (0.06 to 0.57 in/hr)
StF	Steep land, alluvial materials	1.6	0.39%		Undetermined (assume moderate infiltration)
VaB	Vandalia silty clay loam, 3 to 10 percent slopes	4.6	1.11%		Moderately low to moderately high (0.06 to 0.57 in/hr)
VaD3	Vandalia silty clay loam, 20 to 30 percent slopes, severely eroded	4.2	1.01%		Moderately low to moderately high (0.06 to 0.57 in/hr)
VaE	Vandalia silty clay loam, 30 to 40 percent slopes	8.3	2.00%		Moderately low to moderately high (0.06 to 0.57 in/hr)
VaE3	Vandalia silty clay loam, 30 to 40 percent slopes, severely eroded	2.2	0.53%		Moderately low to moderately high (0.06 to 0.57 in/hr)
WeC	Wheeling fine sandy loam, 10 to 20 percent slopes	5.1	1.23%		Moderately high to high (0.57 to 1.98 in/hr)
WhA	Wheeling silt loam, 0 to 3 percent slopes	39.5	9.53%		Moderately high to high (0.57 to 1.98 in/hr)
WhB	Wheeling silt loam, 3 to 8 percent slopes	21.2	5.11%		Moderately high to high (0.57 to 1.98 in/hr)
	Totals for Area of Interest	414.5	100.00%		

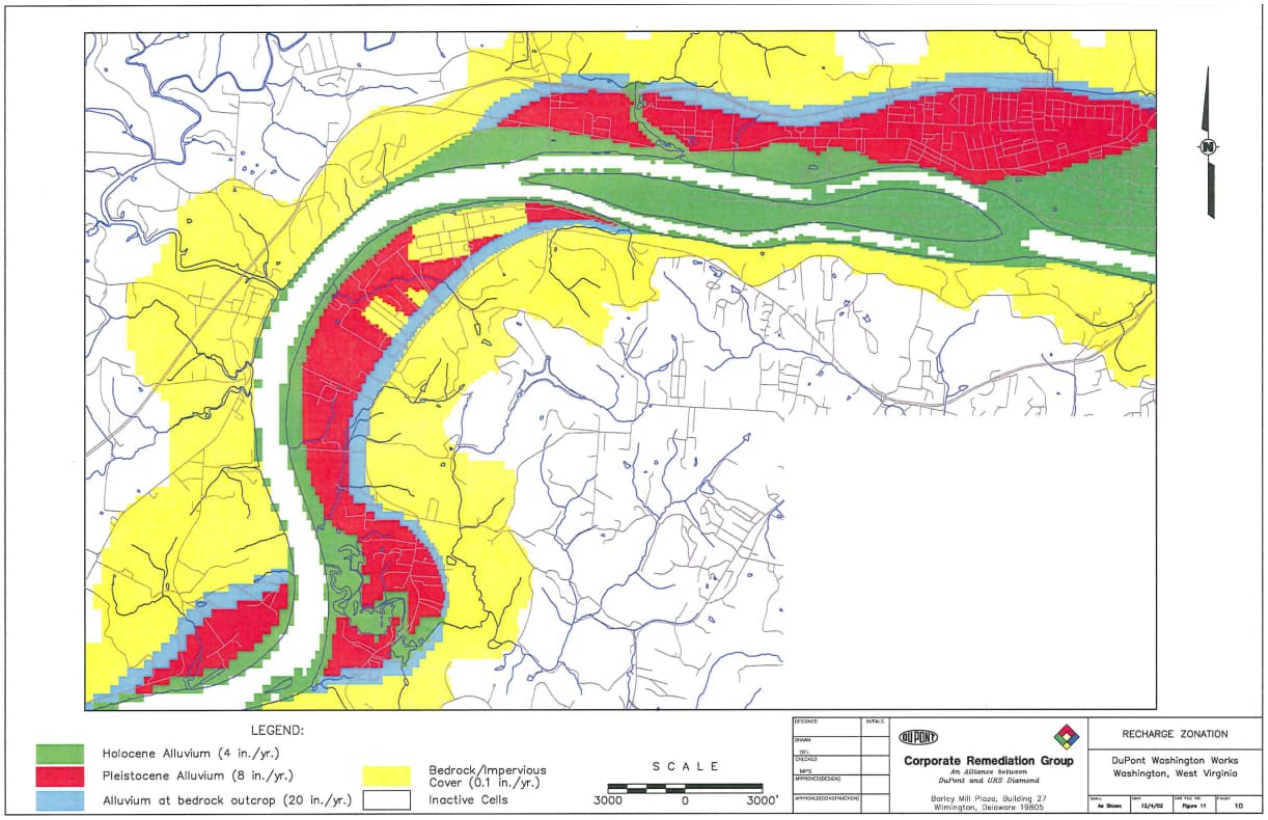
	Acreage of vegetated soils	
	Ksat	Acreage
	High to very high (5.95 to 19.98 in/hr)	0.3
	Moderately high to high (0.57 to 1.98 in/hr)	165.4
	Moderately low to moderately high (0.06 to 0.57 in/hr)	19.3
	Very low to moderately low (0.00 to 0.06 in/hr)	20

Areal estimates shown are from a custom soil report made using the USDA’s Web Soil Survey. https://websoilsurvey.nrcs.usda.gov/app/

Estimated Water Balance – Estimating Current Infiltration to Aquifer

- The site groundwater model was calibrated and adjusted the recharge zones to the alluvial aquifer.
- About half of the unpaved area (Pleistocene Alluvium) was set to 8 inches per year. The other half is split between coarse alluvium at the bedrock outcrop 20 in/yr and Holocene Alluvium (4 in/yr).

(figure from: 2003 Groundwater Modeling Report)



(Note that the current groundwater flow model had calculating 240 acre-feet pear year at the Site.)

Estimated Water Balance – Infiltration

Based on the information in the Groundwater Modeling Report and the USDA soil reports. A calculation has been made estimating infiltration

Assumptions:

Infiltration is assumed to be active on unpaved areas and vegetated soils. Rates from the model were used and applied over approximated areas.

Water that infiltrates is assumed to reach the water table (as opposed to water stored in shallow soils and later evaptranspired).

Infiltration to aquifer		
Unpaved "made land"	4	inch/year
Area of unpaved made land	69.597	acres
Infiltration through unpaved made land	23.199	acre-feet per year
Holocene Alluvium (~25% of vegetated soils)	4	inch/year
Area of Holocene Alluvium	51.375	acres
	17.125	acre-feet per year
Pleistocene Alluvium (~50% of vegetated soils)	8	inch/year
Area of Pleistocene Alluvium	102.75	acres
	68.5	acre-feet per year
Alluvium at Bedrock outcrop (~25% of vegetated soils)	20	inch/year
Area of alluvium at outcrop	51.375	acres
	85.625	acre-feet per year
Estimated Infiltration to aquifer:	194	acre-feet per year

Estimated Water Balance – Evapotranspiration

Actual evapotranspiration (Evt) estimate from the USGS map is approximately 750 mm/yr.

Assumptions:

This Evt is most applicable for vegetated areas. Areas with limited vegetation will have reduced rates and evapotranspiration from paved areas is assumed to be negligible.

This approach assumes that the loamy shallow site soils can store sufficient water so that vegetation does not become inactive in summer.

Evapotranspiration from near-surface soils		
Evapotranspiration per year (from USGS)	750	mm/yr
conversion	10	mm/cm
conversion	2.54	cm/in
Evapotranspiration per year	29.53	in/yr
Evt rate from unpaved "made land"	14.76	inch/year
Area of unpaved made land	69.60	acres
Evt from unpaved made land	85.63	acre-feet per year
Evt rate from vegetated soils	29.53	inch/year
Area of vegetated soils	205.50	acres
	505.66	acre-feet per year
Estimated Evapotranspiration from near-surface site soils:	591	acre-feet per year

Estimated Water Balance – Estimate Runoff to Outfalls

Simplifying assumptions:

Precipitation landing on impervious surfaces runs off (assume no evapotranspiration (Evt) or infiltration)

Precipitation to unpaved areas (vegetated soils) is subject to Evt and infiltration first, but precipitation exceeding those factors must runoff.

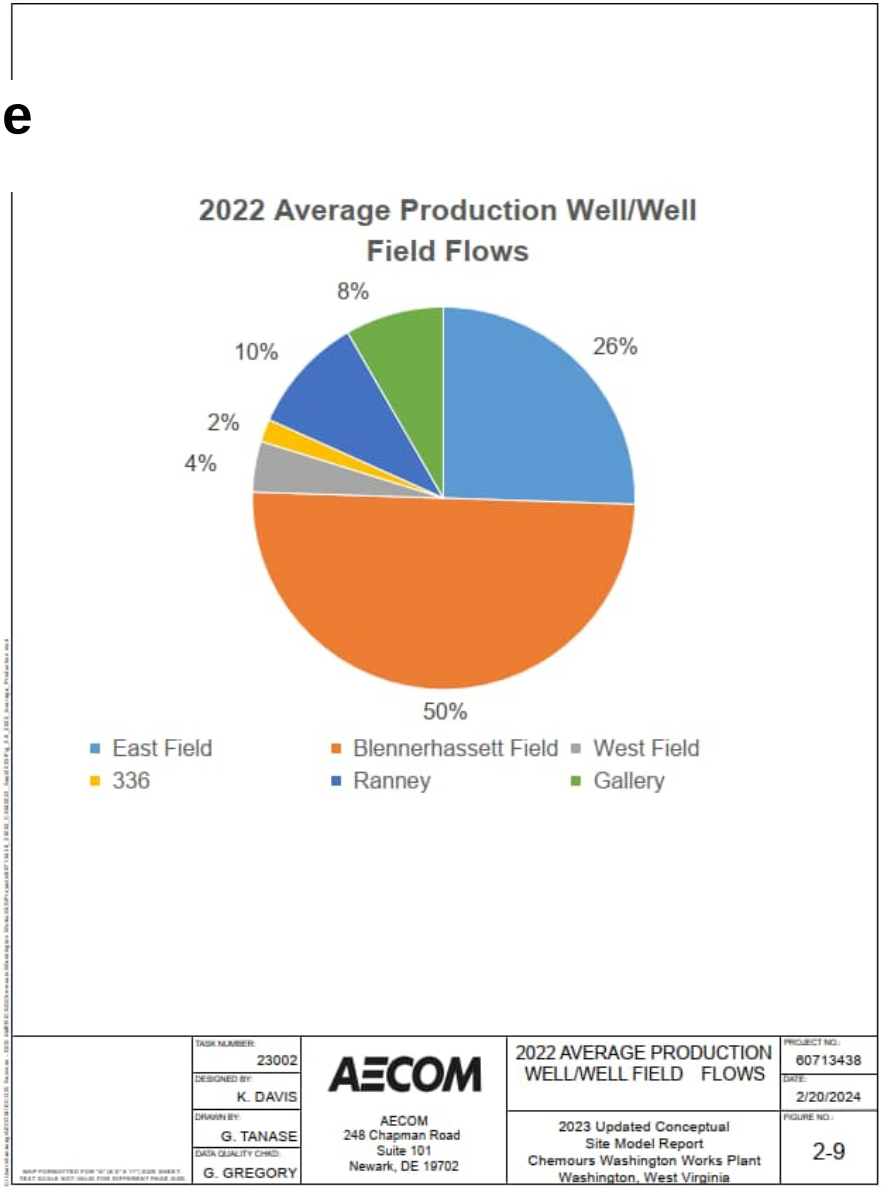
After losses from evapotranspiration and infiltration, there is approximately **389 to 872 acre-feet per year** of stormwater excess that is calculated to go to outfalls.

Runoff Estimate:		
Annual Rainfall volume (low end)	1,174	acre-feet per year
Annual Rainfall volume (high end)	1,658	acre-feet per year
Simplifying assumption: assume that runoff total is the precipitation in excess of infiltration and Evt		
Subtract: Infiltration from unpaved made land	23.20	acre-feet per year
Subtract: Infiltration from vegetated soils	171.25	acre-feet per year
Subtract: Evapotranspiration from unpaved made land	85.63	acre-feet per year
Subtract: Evapotranspiration from vegetated soils	505.66	acre-feet per year
Total of Evt and infiltration	785.73	acre-feet per year
Net runoff (low end precipitation)	388.68	acre-feet per year
Net runoff (high end precipitation)	872.27	acre-feet per year

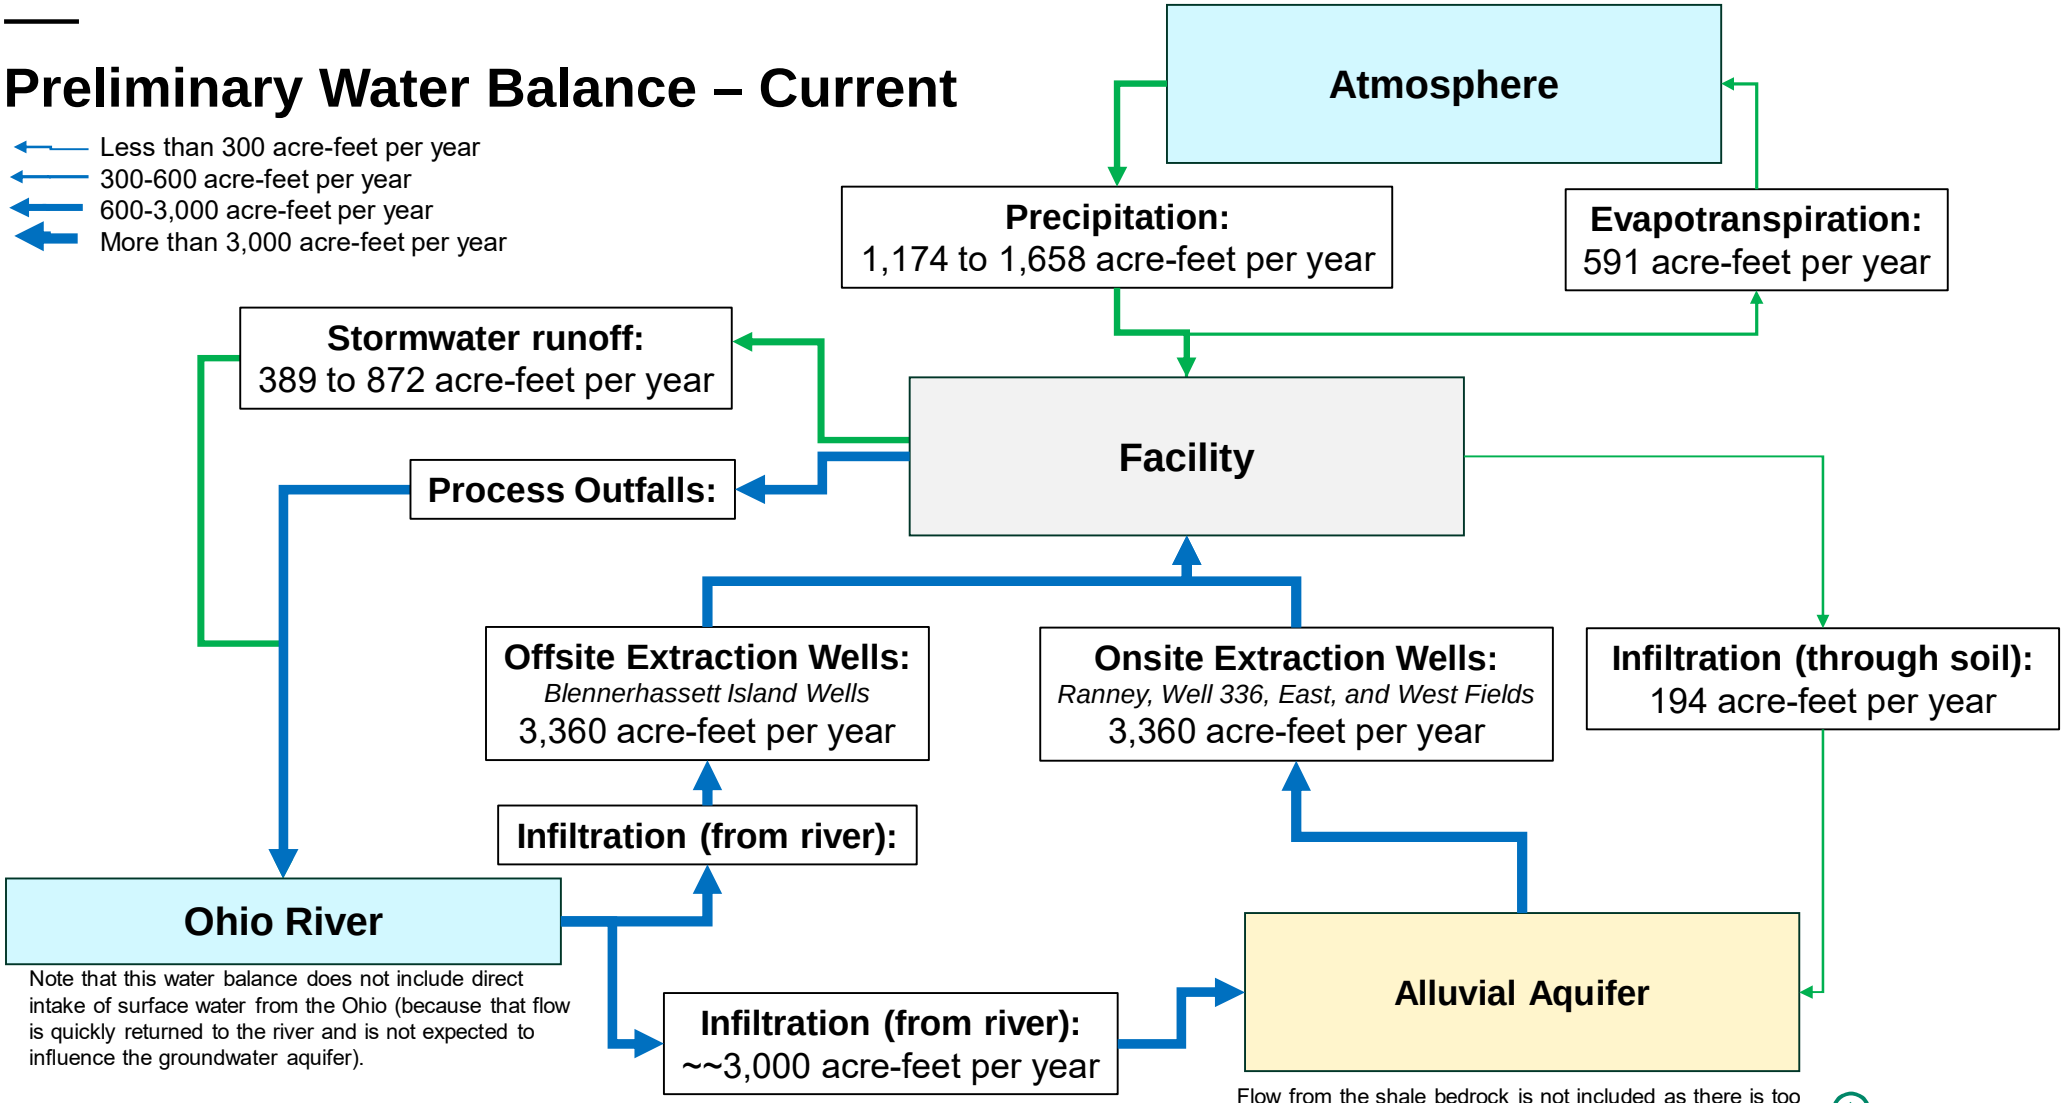
Estimated Water Balance – Process Water Use

- Current **site production processes use** 6 million gallons of groundwater per day[1] (mgd) (18.41 acre-feet per day or **6,721 acre-feet per year**).
- Approximately half of the site process water comes from wells on Blennerhassett Island (does not affect site containment).
- **Ranney Well** is **currently 10%** of the flow (672.1 acre-feet per year)
- **Ranney Well** has been **upgraded** with a 1,750 gpm treatment system (7.73 acre-feet per day; **2,823 acre-feet per year**).

1: 2022 Routine Monitoring and Corrective Measures Assessment Report.



Preliminary Water Balance – Current



Note that this water balance does not include direct intake of surface water from the Ohio (because that flow is quickly returned to the river and is not expected to influence the groundwater aquifer).

Flow from the shale bedrock is not included as there is too little information to estimate and is believed to be minor.

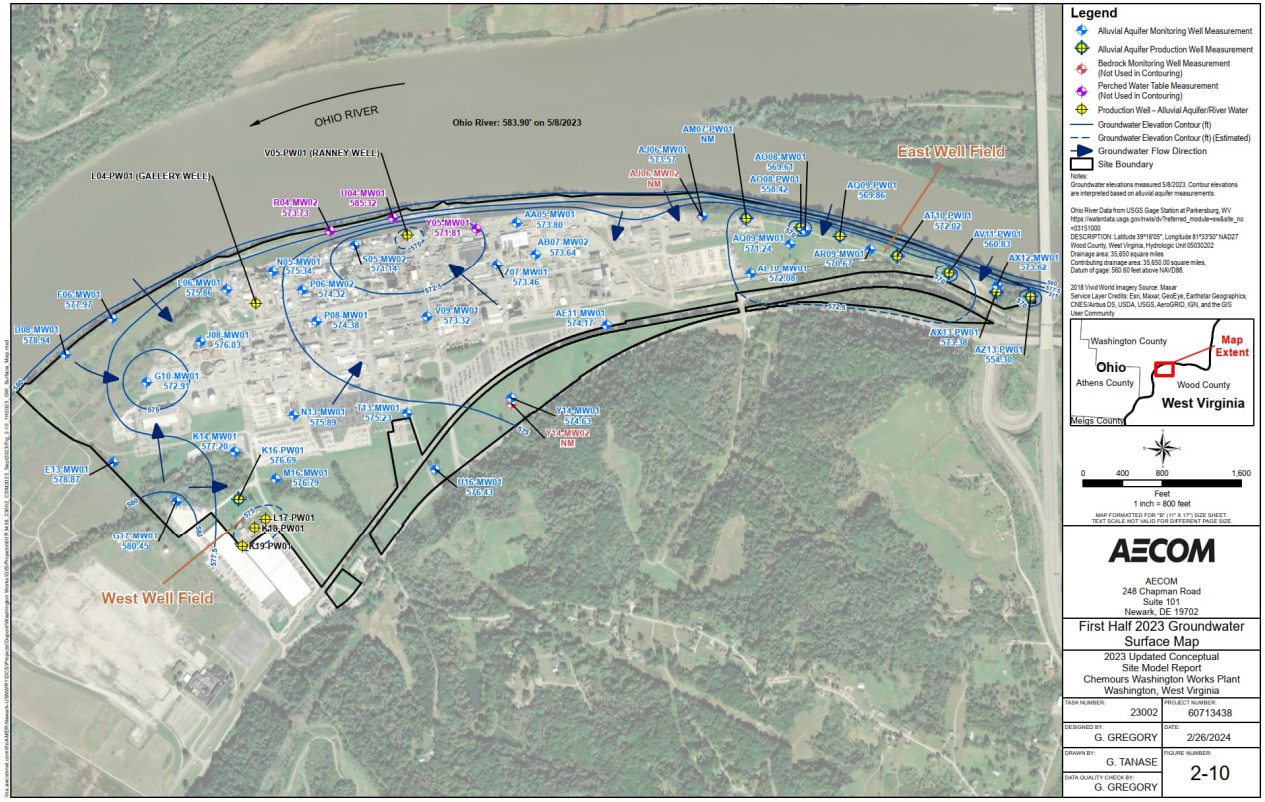
Hydraulic Containment of Groundwater – Potentiometric Surface

Arrows indicate flow direction

Water table near Ranney Well is approximately 572 feet (~11 feet lower than the Ohio River stage).

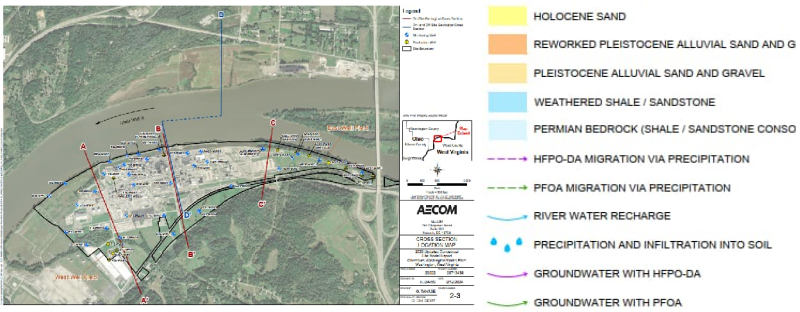
East and West Well Fields also drawdown the water table.

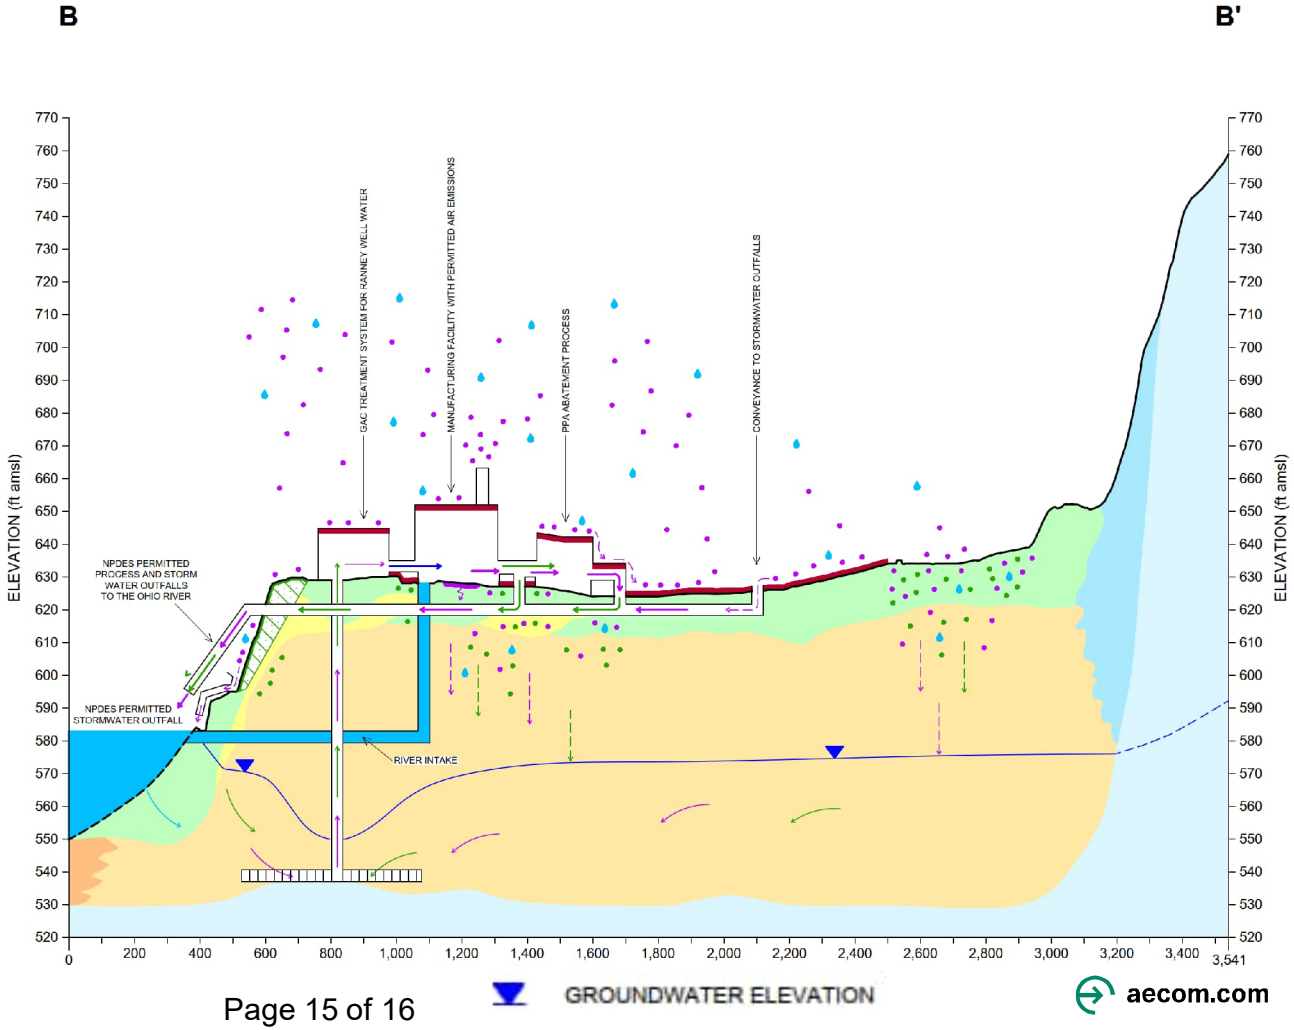
Due to the constant pumping from the site production wells, there is always an ***inward hydraulic gradient.***



Hydraulic Containment of Groundwater – Cross Sectional View

Because of the extraction system, the **water table is lower than the river** and flow is toward the extraction wells.





Ranney Well has Extra Capacity

Ranney Well currently operates at 1.841 acre-feet per day; (672.1 acre-feet per year), but it could be raised to 7.73 acre-feet per day (2,823 acre-feet per year).

Upgrade of Ranney Well GAC Treatment

- Ranney Well is <u>able</u> to pump *and treat* 1,750 gpm (7.73 acre-feet per day). The image at right is the <u>modeled</u> water table <u>if</u> Ranney operates at that rate.
- **Ranney Well could provide an additional 2,151 acre-feet per year** from the aquifer if needed.

Appendix C Laboratory Reports

1.0 Introduction

U.S. Environmental Protection Agency (EPA) issued an Administrative Compliance Order on Consent (ACO) under Section 309(a) of the Clean Water Act, 33 U.S.C. § 1319(a) to The Chemours Company FC, LLC (Chemours) Washington Works Facility (Site) in Parkersburg, West Virginia, on April 5, 2023.

Section III.44. of the ACO requires Chemours to implement the *Field Sampling Plan for Administrative Order on Consent (AOC) Sample Collection* prepared by Chemours in March 2023 (Sampling Plan; included as Exhibit 3 of the ACO) to characterize the nature of the stormwater runoff and effluent wastewater leaving the Site. This Sampling Plan described conducting specified per- and polyfluoroalkyl substances (PFAS) sampling to identify and quantify PFAS discharges at each permitted outlet using draft EPA Method 1621 (for absorbable organic fluorine), draft EPA Method 1633, total oxidizable precursor (TOP) assay, and non-targeted analysis (NTA).

As described in the Sampling Plan, samples were to be collected during normal operations when the facility was manufacturing and/or processing PFAS. “Normal operations” included all operating periods other than periods associated with startup, shutdown, equipment malfunction, or upset. Samples were to be grab samples collected at the time of day when typical, representative wastewater volumes were expected (including stormwater component to mixed discharges). Prior to the sampling event, it was also determined that a precipitation event of approximately 0.3 inches of rain were needed for there to be sufficient flow in the outlets for sampling to occur. Stormwater and wastewater outlets were sampled on March 26, 2024.

As of early June 2024, results for analytical methods except the NTA had been finalized and those results were submitted to EPA in the *Administrative Compliance Order on Consent – Per- and Polyfluoroalkyl Substances (PFAS) Analysis of Stormwater Runoff and Effluent Wastewater at the Chemours Washington Works Facility* technical memo on June 12, 2024 (see Appendix A).

In September 2024, the NTA results were finalized. This report includes details of the sampling event (field readings, field sheets, and photographs of stormwater outlets), the analytical results for the four methods used including the laboratory reports, and a summary of observations on the results.

2.0 Sampling Activities

2.1 Sampling Locations

As described in Section 1.3 of the Sampling Plan, water was sampled from the following process water effluent and stormwater outlets:

- Process Water Effluent Outlets:
  - 001
  - 002
  - 003
  - 005
  - 006
  - 007
- Stormwater Outlets
  - 011
  - 016
  - 022
  - 023
  - 025
  - 030
  - 031
  - 032
  - 033
  - 034
  - 036

Figure 1 shows the process water effluent and stormwater outlets listed above.

2.2 Precipitation Monitoring

As per Section 2.1 of the Sampling Plan, samples were collected during normal operations when the facility was manufacturing and/or processing PFAS with “Normal operations” including all operating periods other than periods associated with startup, shutdown, equipment malfunction, or upset.

Based on Site knowledge, it was understood that in order for there to be flow in the stormwater outlets, a rainfall event of a specific amount and or duration would be required. Once the NTA procedures and validation process were approved by EPA on September 15, 2023, precipitation conditions were monitored closely. A precipitation event of the required amount and/or duration had not yet occurred during routine working hours and under storm conditions such that the samples could safely be taken as of March 2024. On March 26, 2024, rain started at 7:00 AM. Outlets started having flow approximately noon, and sample collection began as described in Section 2.3 below. In total, 1.05 inches of rain fell during this precipitation event.

2.3 Sample Collection

As per Sections 1.7 and 1.8 of the Sampling Plan, grab sampling was performed at the outlets. Field measurement monitoring was completed as described in Sections 2.3 and 3.2 of the Sampling Plan. Sample labeling was completed as described in Sections 2.5

and 3.0 of the Sampling Plan, and field sample handling and Chain-of Custody were completed as per Section 3.3 of the Sampling Plan. Collection of grab samples was completed as described in Section 2.7 of the Sampling Plan and was started at 12:45 PM and was completed by 2:10 PM. However, Outlet 019 was not flowing at the time the grab samples were collected; therefore, no sample could be collected. Quality control (QC) samples were collected as per Section 2.7.2 of the Sampling Plan. Field QC samples included an equipment blank, a field blank ,and a field duplicate and were prepared by the laboratory as per Section 2.7.3 of the Sampling Plan with the contract laboratory performing QC for these supplies as specified in their standard operating procedures, such as analyzing blanks for each lot of sample containers and blank water. Sample packing and shipment was completed as per Section 2.8 of the Sampling Plan.

Data verification is a completeness check to confirm that required activities were conducted, specified records are present, and the contents of the records are complete. Field data verification procedures were completed as per Section 4.0 of the Sampling Plan. Appendix B provides the field readings, field sheets, and photographs of stormwater outlets. No photographs were taken of the process water effluent outlets.

3.0 Analytical Methods

As described in the Sampling Plan, outlet samples were to be analyzed via four methods by contract laboratory Eurofins Lancaster Laboratories Environmental (ELLE) Testing, LLC (located in Lancaster, Pennsylvania) or Eurofins Environment Testing (located in West Sacramento, California) as indicated below:

- Draft EPA Method 1633 analyzed by ELLE
- TOP assay referencing methods described in *Oxidative Conversion as a Means of Detecting Precursors to Perfluoroalkyl Acids in Urban Runoff* (Houtz and Sedlak, 2012) with the analysis for PFAS (before and after TOP procedure) via 537 Modified analyzed by ELLE
- NTA was conducted as described in the *Non-Targeted Analysis (NTA) Procedure and Validation* developed by Eurofins Environment and approved by EPA on September 15, 2023, with analysis performed by Eurofins Environment. (The NTA Procedure is provided in the laboratory report for the NTA, which is provided in Appendix C.)
- Draft EPA Methods 1621 for absorbable organic fluorine analyzed by ELLE

As per Section 2.7.3 of the Sampling Plan, with the exception of the NTA analyses, the laboratories used standard analytical methods, conducted using method-specific standard operating procedures developed based on method requirements, and the laboratories complied with the quality assurance and QC requirements specified in 40 CFR §136.7. Laboratory data verification procedures were completed as per Section 4.0 of the Sampling Plan. Data validation procedures were completed as per Section 5.0 of the Sampling Plan.

As per Section 5.4 of the Sampling Plan, laboratory reports are included in Appendix C. Laboratory reports include raw data submitted to EPA in electronic form. This includes all raw instrument data files, the complete feature table with data processing details, the complete dataset with all the picked/annotated features, the annotations (accurate mass, formula predictions, IDs, scores, etc.), abundances, and the feature chromatograms.

4.0 Analytical Results and Observations

4.1 Analytical Results

Table 1 provides the DRAFT EPA method 1633 results, the TOP assay results, and the DRAFT EPA Method 1621 results. Results for the NTA are provided in the laboratory report narrative. Results for the NTA showed only one sample, 016-032624, which was collected from stormwater Outlet 016, for which one "suspect analyte" was identified. The suspect analyte in the sample from Outlet 016 was identified as hydrogen-substituted perfluorohexanoic acid.

4.2 Chemours' Observations

For the DRAFT EPA Method 1633 results, Chemours notes the following:

- The results presented here for process water effluent and stormwater outlets at the Site align with the results presented in the Tables 5-11 and 5-13 in the *2023 Updated Conceptual Site Model Report* (submitted to EPA on March 4, 2024). Tables 5-11 and 5-13 provide a summary of the PFAS results for the Site process outlets and stormwater outlets, respectively, between August 2018 through December 2023. The data in those tables show that perfluorooctanoic acid (PFOA) and hexafluoropropylene oxide dimer acid (HFPO-DA), in general, have the maximum concentrations, which are an order of magnitude or two above a second set of PFAS (3 to 6 depending on location), which are an order of magnitude higher in concentration than a handful of PFAS (again, 3 to 6 depending on location) in the low to single digit nanograms per liter (ng/L) range.
- The new results presented here show the same trend in concentrations with HFPO-DA and PFOA present typically at an order of magnitude higher than a second set of 3 to 4 PFAS, which vary depending on location at the Site and which are present at an order of magnitude above a third set of 3 to 4 PFAS which are present at low ng/L concentrations.
- Notably, sulfonate PFAS (perfluorooctane sulfonic acid [PFOS], perfluorohexane-1-sulphonic acid [PFHxS], perfluorobutane sulfonate [PFBS]) are present at very low to less than the reporting limit concentrations in this data set.

For the TOP assay results, Chemours notes the following:

- Comparing the "Pre" and "Post" sample pair results, most of the "Post" results show lower concentrations than the "Pre," which indicates that there are no precursors present in the Site process water effluent and stormwater samples.

For the NTA results, Chemours observes the following:

- Only one of the 20 samples, a stormwater sample collected at Outlet 016, showed the presence of suspect analytes and only one suspect analyte was identified.
- Nineteen of the 20 process water effluent and stormwater outlet samples were shown to have no non-targeted compounds identified, which indicated that there are no unknown PFAS or precursors present in these samples.

- The combination of results from these three methods support that the PFAS chemistry at the Site is well characterized and that there are no precursors present.

Because the AOF method is relatively new, Chemours declines to make observations on this data set.

5.0 Summary of Observations

For this project, process water effluent and stormwater outlet samples were collected from 19 locations at the Site on March 26, 2024. These samples were analyzed using three targeted methods, DRAFT EPA Method 1633, TOP assay, and Draft EPA Methods 1621 for absorbable organic fluorine, and also by NTA.

No observation was made on the absorbable organic fluorine as the method is relatively new. Nineteen of the 20 process water effluent and stormwater outlet samples were shown to have no non-targeted compounds identified, which indicated that there are no unknown PFAS or precursors present in these samples. The combination of results from the DRAFT EPA Method 1633, TOP assay and NTA support that the PFAS chemistry at the Site is well characterized and that there are no precursors present.

Memo

Subject: Administrative Compliance Order on Consent – Per- and Polyfluoroalkyl Substances (PFAS) Analysis of Stormwater Runoff and Effluent Wastewater at the Chemours Washington Works Facility

Introduction

U.S. Environmental Protection Agency (EPA) issued an Administrative Compliance Order on Consent (ACO) under Section 309(a) of the Clean Water Act, 33 U.S.C. § 1319(a) to The Chemours Company FC, LLC (Chemours) Washington Works Facility in Parkersburg, West Virginia, on April 5, 2023.

Section III.44. of the ACO requires Chemours to implement the *Field Sampling Plan for Administrative Order on Consent (AOC) Sample Collection* prepared by Chemours in March 2024 (Sampling Plan; included as Exhibit 3 of the ACO) to characterize the nature of the stormwater runoff and effluent wastewater leaving the site. This Sampling Plan described conducting specified per- and polyfluoroalkyl substances (PFAS) sampling to identify and quantify PFAS discharges at each permitted outlet using draft EPA Method 1621 (for absorbable organic fluorine), draft EPA Method 1633, total oxidizable precursor (TOP) assay, and non-targeted analysis (NTA).

To date, results for analytical methods except the NTA have been finalized. This memo provides those results. A final report will be issued once the NTA results are finalized and will include the field notes, the analytical results, and the laboratory reports.

Sampling Activities

As described in the Sampling Plan, samples were to be collected during normal operations when the facility was manufacturing and/or processing PFAS. “Normal operations” included all operating periods other than periods associated with startup, shutdown, equipment malfunction, or upset. Samples were to be grab samples collected at the time of day when typical, representative wastewater volumes were expected (including stormwater component to mixed discharges). Prior to the sampling event, it was also determined that a precipitation event of approximately 0.3 inches of rain was needed for there to be sufficient flow in the outlets for sampling to occur.

Stormwater and wastewater outlets were sampled on March 26, 2024. As described in the Sampling Plan, water was sampled from the following process water effluent and stormwater outlets:

- Process Water Effluent Outlets:
  - 001
  - 002
  - 003
  - 005
  - 006
  - 007
- Stormwater Outlets
  - 011
  - 016
  - 022
  - 023
  - 025
  - 030
  - 031
  - 032
  - 033
  - 034
  - 036

Stormwater Outlet 019 was proposed for sampling. A total of 1.05 inches of precipitation fell on the day of the sampling. However, Outlet 019 was not flowing, and no sample could be collected. Figure 1 (attached) show the location of the outlets sampled, as well as Outlet 019.

Analytical Methods

As described in the Sampling Plan, outlet samples were to be analyzed via four methods:

- Draft EPA Method 1621 (for absorbable organic fluorine)
- Draft EPA Method 1633
- TOP assay referencing E.F. Houtz, D.L. Sedlak *Oxidative conversion as a means of detecting precursors to perfluoroalkyl acids in urban runoff* Environ. Sci. Technol., 46 (2012), pp. 9342-934 and the actual analysis for PFAS (before and after TOP procedure) 537 Modified)
- NTA to be conducted as described in the *Non-Targeted Analysis (NTA) Procedure and Validation* developed by contract laboratory Eurofins Lancaster Laboratories (located in Lancaster, Pennsylvania) and approved by EPA in the fall of 2023.

Analytical Results

To date, results for analytical methods except the NTA have been finalized. Table 1 (attached) provides these analytical results. As stated above, a final report will be issued once the NTA results are finalized and will include the field notes, the complete set of analytical results and the laboratory reports.

STORM EVENT LOG

02-22-2024 – Rain started approximately 0600. Outfalls did not start flowing until 1530 to 1545 and thunderstorms and lighting had moved into the area. Unable to collect samples due to thunderstorms in the area.

02-28-2024 – Rain started roughly 0730 and reached our needed amount for there to be flow at the outfalls but the rain did not continue. According to the sampling plan we must have continued rainfall for the sampling event. Rain was very light and sporadic. It would stop and start with no heavy periods of rainfall.

03-15-2024 – Rain started around 0039 and continued with some thunderstorm activity until approximately 0400, where the amount reached 0.47". Outfalls were checked at 0830 and had stopped flowing. Rain had been forecasted to last the entire day but did not start again.

03-26-2024 – Rain started at 0700 and ended at roughly 1900. Outfalls started having flow approximately noon. Sampling started at 1245 and was completed at 1410.

EPA 2006 RFI Approval Letter

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
REGION III
1650 Arch Street
Philadelphia, Pennsylvania 19103-2029
February16, 2006

Mr. Andrew Hartten
DuPont Engineering
Project Director
Barley Mill Plaza - Bldg 27
Lancaster Pike & Route 141
Wilmington DE 19805

RE: Approval of RCRA Facility Investigation Report

Dear Mr. Hartten:

This letter is to inform you that EPA Region III has approved the RCRA Facility Investigation Report for DuPont Washington Works in Washington, West Virginia. The investigation characterized solid waste management unit (SWMU) related contaminants and provided the information necessary to move forward with a Corrective Measures Study (CMS) for the facility. The purpose for the CMS will be to evaluate the best remedial action to implement at the various SWMUs. The approval for this RFI report was delayed as a result of the on-going investigations into the toxicity and the extent of contamination of the site-related compound, ammonium perfluorooctanoate (PFOA). At this time Region III believes that the PFOA information gathered during the past few years will not affect the site characterization completed during the RFI. The new information obtained and any additional information that is generated from on-going investigations will be evaluated during the CMS and will be incorporated into the remedy selection process.

If you have any questions or I can be of further assistance, please contact me at (215) 814-3184.

Sincerely,

William C Wentworth

Washington Works Site Groundwater Capture Update and Basis for Financial Assurance Calculation

Initial: January 2021
Revised: April 2021

July 21, 2021

Washington Works RCRA Corrective Action Final Remedy Groundwater Capture Financial Assurance Calculation

- The defined RCRA Final Remedy for Washington Works requires the site to maintain groundwater capture/inward gradient by production well pumping and to treat that water prior to discharge.
- In order to update the RCRA Financial Assurance calculation for costs related to groundwater capture, this presentation has been prepared to document relevant pumping rate and annual treatment volume.
- This documentation includes:
  - Elements of original 2003 Groundwater Modeling report,
  - Updated estimate of minimum essential pumping needed (i.e.; Ranney Well) to maintain groundwater capture/inward gradient, and
  - Estimated annual cost to run new Ranney Well granular activated carbon (GAC) treatment system, when operational.

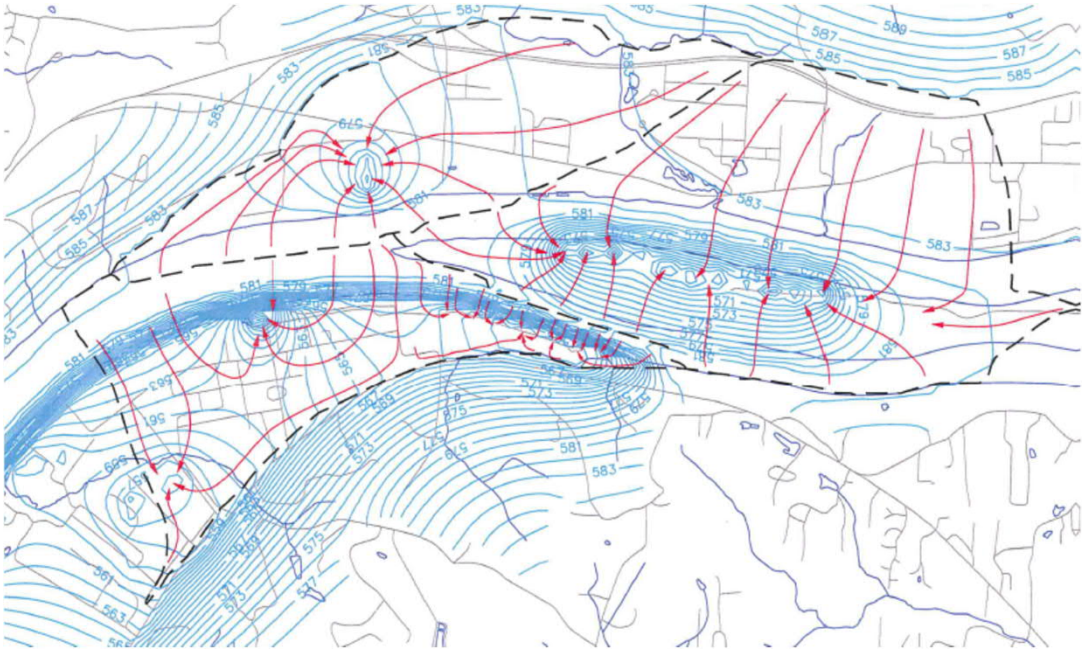
Chemours™

Washington Works Site Groundwater Facts

- The Washington Works site uses approximately 10 million gallons a day (MGD) of pumped groundwater for production uses.
- The groundwater comes from the Ranney Well, the East Field, and the West Field (all on-site) and the Blennerhassett Island pumping centers.
- Blennerhassett Island groundwater is not hydraulically connected to main plant groundwater and is not relevant to maintaining site groundwater capture.
- The 2003 Groundwater Model showed site production well pumping easily maintains site groundwater capture/inward gradient.
- Former GE/Sabic plant to west no longer pumps groundwater and any influence of their pumping no longer exists.
- Recent (2021) groundwater modeling simulations show that pumping of Ranney Well alone will maintain site groundwater capture.
- **Key Note: If the entire site shut down operations, only the Ranney Well would need to be pumped and treated long term to maintain Final Remedy requirement**

2003 Groundwater Model

- The 2015 WVDEP Statement of Basis recognized that site groundwater capture is maintained by production well pumping as demonstrated in the 2003 Groundwater Model Report.
- Typical Site Pumping Conditions (2003 Report Figure 14-A)

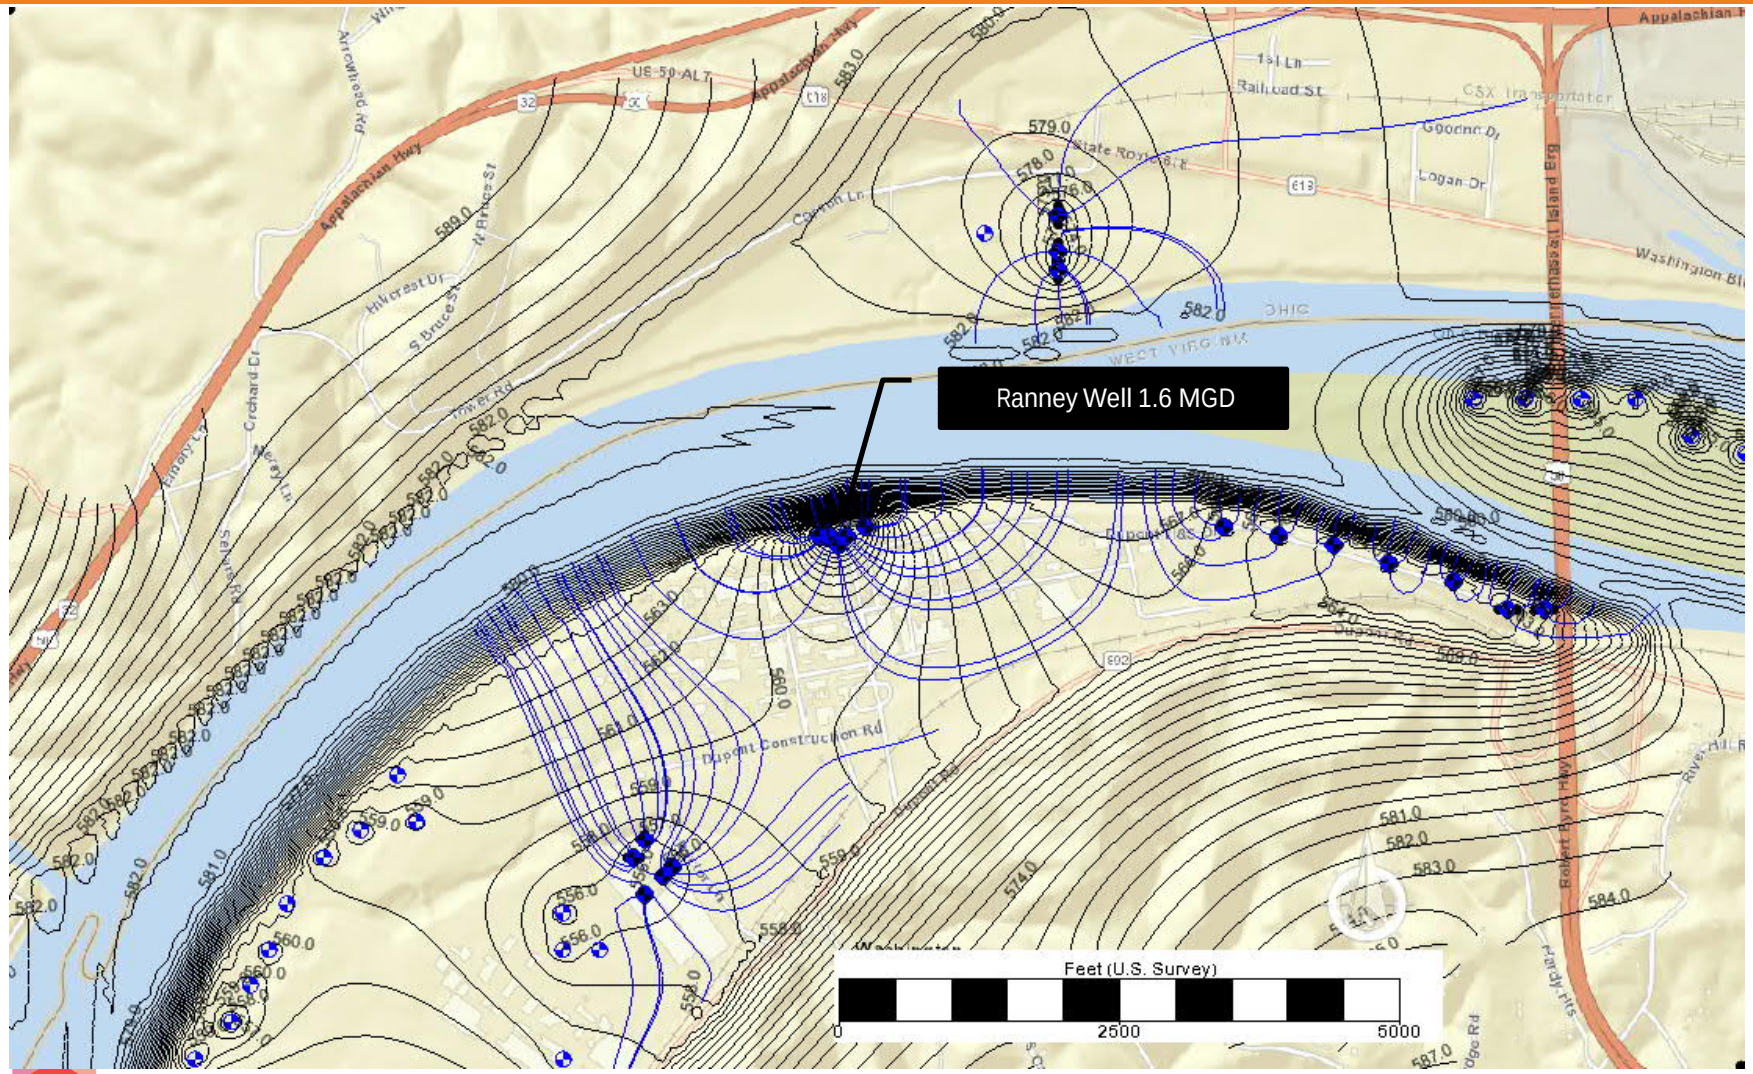


Chemours™

Revised Modeling - 2021

- In March 2021, the MODFLOW groundwater flow model for the Washington Works and surrounding area (DuPont, 2003) was used to simulate the groundwater surface and resultant groundwater control assuming actual and reduced flows at the Ranney well. MODPATH was used to track predicted groundwater flow.
- The first simulation was to confirm current conditions with all wells/well fields operating at current flow rates.
- During 2019 and 2020, Ranney Well has been operating at 1.6 MGD.

2021 Modeling - Current Conditions (all wells on)



Particle tracks run backward in time from pumping wells
Ranney well flow based on yearly average of 2019 and 2020 flow

2021 Modeling – Hypothetical Conditions

- The next set of simulations were performed to test hydraulic capture under the conditions expected if the site were to be shut down. In that situation, it is assumed that only the Ranney well will be in operation.
- Figures displaying the predicted potentiometric surface maps with only the Ranney Well in operation are provided as Figures 5.5 through 5.7.
- Figure 5.5 shows the predicted groundwater surface map for the Ranney Well pumping at the 2019/2020 annual average flow of 1.6 million MGD.
- Figures 5.6 and 5.7 show the predicted groundwater surface maps for the Ranney Well pumping at reduced flow rates of 75 per cent (%) and 50%, respectively, of the 2019/2020 annual average flow of 1.6 MGD.
- Hydraulic containment of on-site groundwater is predicted by the inward hydraulic gradient even in the 50% scenario, which represents Ranney Well operating at 0.8 MGD.

Modeled Flow – Ranney Well at 1.6 MGD (100%)

- With flow at 1.6 MGD, Ranney well has a very wide zone of capture, extending more than a mile from the well.
- This pumping rate is predicted to capture all flow in the aquifer under the site.

Chemours™

Basis For Financial Assurance Estimate
Groundwater Pumping to Maintain Sitewide Capture

- The Washington Works facility can maintain sitewide groundwater capture (inward gradients) solely through Ranney Well pumping. Assuming continuous operation, the Ranney well can contain groundwater across the site even at 50% of the 2019/2020 rate (0.8 MGD).
- Ranney Well average pumping rate for 2019/2020 was 1.6 MGD. This groundwater extraction rate is used for FA calculation and provides ample excess drawdown to maintain control of groundwater under the site.

(References: 2019 and 2020 Long Term Groundwater Monitoring Report-Production Well Pumping Rates and Figures 5.5 through 5.7 of the 2020 CMI Annual Report)

Basis For Financial Assurance Estimate
Groundwater Pumping to Maintain Sitewide Capture

The Washington Works site is currently constructing a GAC system to treat the Ranney Well production water that will be operational in late September 2021.

- The GAC treatment system was designed to remove PFOA and other site constituents
- The treatment system is under construction and is scheduled to be operational in September.
- Average daily system operation is anticipated to be 1,400 gpm (2 MGD).
- OM&M for the system will require use of 140,000 pounds of GAC per year (2 system change outs per year) and routine sampling and analysis.

Financial Assurance Initial Cost Estimate

In the FA calculation, the following assumptions were used:

- Average daily system operation to maintain hydraulic control is 1.6 MGD based on the 2019/2020 average flow and assuming Ranney Well is the only well in operation
- Annual treatment costs based on 1.6 MGD:
  - Analytical cost: $12,500 (same sampling program as for 2 MGD)
  - Based on one change out (70,000 pounds) of GAC every 9 months, GAC and OM&M cost: $150,000 per year
