1.0 Introduction

This Per- And Polyfluoroalkyl Substances (PFAS) Statistical Forensics Analysis Report presents an expanded evaluation of PFAS in private drinking water sources in Ohio and West Virginia in the vicinity of the Chemours Company FC, LLC (Chemours) Washington Works Plant (the site).

On March 4, 2024, Chemours submitted the *2023 Updated Conceptual Site Model Report* to Ms. Susanne Haug, Remedial Program Manager, U. S. Environmental Protection Agency Region 3 (EPA). That report documented the revisions to the Conceptual Site Model (CSM) for the site, located in Washington, West Virginia and presents the On-Site and Off-Site CSMs for the site updated in 2023, which include key site and other agencies' PFAS sampling results through 2023.

As part of this CSM update, AECOM developed concentration maps (dot maps), which depict the concentrations of various PFAS in private (residential) drinking water sources in the vicinity of the site in Ohio and West Virginia (see Figures 6-6 through 6-17 of the *2023 Updated Conceptual Site Model Report)*. The objective of the dot map evaluation was to determine if the drinking-water well data set showed trends in the spatial distribution of individual PFAS within the investigation area.

The results of the dot map evaluation showed that there are similar patterns in the distribution of perfluorooctanoic acid (PFOA), perfluorohexanoic acid (PFHxA), perfluoroheptanoic acid (PFHpA) and to a lesser extent hexafluoropropylene oxide dimer acid (HFPO-DA; commonly referred to as GenX). For these PFAS, concentrations are higher closer to the site and in the primary wind direction to the northeast and decrease with increasing distance from the site. PFHxA and PFHpA were residuals in the ammonium perfluorooctanoate used at the site until 2000, so it is not unexpected that the distribution of these two PFAS would be similar to that of PFOA.

HFPO-DA replaced PFOA as a site processing aid starting in 2013, so the similarities in the presence of PFOA and HFPO-DA are also not unexpected. However, HFPO-DA has been used for a shorter timeframe (2013 through the present compared to the time from the 1950s to 2013), and abatement technologies have been installed that have resulted in reduced concentrations of PFAS in site air emissions overall. Therefore the areal footprint of HFPO-DA is smaller.

In addition, there are localized detections (or hot spots) in the PFOA, PFHxA, and PFHpA dot maps that are higher than surrounding detections, indicating the presence of sources of these three PFAS unrelated to site manufacturing. The presence and distribution of the remaining PFAS detected in the private drinking water sources, particularly the sulfonate PFAS compounds, indicate that these PFAS also likely represent localized hot spot sources and are unrelated to site manufacturing processes.

While informative, the dot map analysis was limited in the conclusions that could be drawn with respect to source determination. To evaluate if unique PFAS fingerprints, defined as distinct, recognizable combinations of PFAS observed in connection with a specific source, could be identified in the drinking-water data set, AECOM performed a PFAS statistical forensics analysis using the same data set as was used for the dot map analysis.

Subject to US/Chemours Settlement Confidentiality Agreement

The remainder of this report is organized as follows:

- Section 2 describes the methodology used for this statistical forensics data analysis, the data set evaluated, and the data preprocessing.
- Section 3 presents the results of the statistical forensics data analysis, including the initial data observations and the isolated PFAS mixture signature groups.
- Section 4 presents the forensics interpretation of the results.
- Section 5 provides the conclusions of the PFAS statistical forensics analysis.
- Section 6 lists the references cited in this report.

2.0 Methodology

Environmental statistical forensics is a multidisciplinary process that makes use of powerful statistical and data analytics methods to assess multiple types of data (e.g., chemical, geospatial, historical, hydrogeological). Pattern-recognition techniques and compositional mixture analysis can be used to identify indicator compounds and contaminant sources for specific chemical families such as PFAS. This section provides additional background information, describes the statistical methods used in this forensic analysis, and summarizes the data included in the analysis, including preprocessing steps.

2.1 Overview of Statistical Forensic Data Analysis

This environmental statistical forensics analysis aims to impartially reveal groupings (i.e., clusters) of similar observations so that relationships within the data set can be successfully explored and modeled. The use of statistical methods such as principal component analysis (PCA) and hierarchical clustering to differentiate chemical mixtures is not new or novel. In the chemical sciences, this approach has been used for decades in a wide range of applications from identifying adulterated food products to discerning distinct petroleum releases (Brereton, 2009). Recently, the widespread accessibility to statistical computing through open-source platforms like R Statistical Software (2023) has grown alongside the need for more powerful tools to investigate PFAS in the environment. This has led to the demonstration of a wide range of statistical applications in PFAS investigations, ranging from the identification of novel PFAS molecules in analytical chemistry applications (McCord and Strynar, 2019) to using PCA and hierarchical clustering to link PFAS mixtures found in blood serum to specific dietary exposure sources (Hu et al., 2018).

The statistical approach applied to the data set in this analysis is consistent with robust combinations of these same methods used by several others to investigate and define PFAS sources (Yao et al., 2014; Zhang et al., 2016; Munoz et al., 2017; Guelfo and Adamson, 2018; Hu et al., 2018; McCord and Strynar, 2019; Stoiber et al., 2020; Luo et al., 2021; Zheng et al., 2021; Ruyle et al., 2021). Based on the broad adoption of these methods in published PFAS research, there is clearly a growing consensus that these multivariate statistical methods provide one of the most valid, effective ways to differentiate and evaluate PFAS sources.

Conceptually, the outcome of the forensic statistical analysis is a multivariate profile referred to colloquially as a PFAS fingerprint. The PFAS mixture proportions for each sample are the inputs that ultimately isolate individual groups with similar PFAS compositions; however, this is only one part of the fingerprinting process. A full fingerprint is defined by the aggregated characteristics of those PFAS mixture groups, including correlations and spatial distribution within the groups, much as an actual fingerprint is a two-dimensional collection of uniquely arranged lines and multiple fingerprints represent a single identity.

2.2 Statistical Methodology

The statistical analyses were performed using R software with a combination of PCA and hierarchical clustering to form an unbiased, unsupervised pattern recognition process. Unsupervised pattern recognition is defined as the statistical grouping of multivariate observations by similar features; in this case, they were grouped by similar

PFAS mixture proportions. These methods can be used to categorize large, complex data sets into groups that exhibit similar chemical attributes (e.g., presence of specific compound[s], relative ratio of compounds, etc.). PCA has been utilized to identify environmental contamination sources (Johnson et al., 2002; Brereton, 2009), and PCA combined with hierarchical clustering has been utilized to identify PFAS source patterns (Zhang et al., 2016; Hu et al., 2018; McCord and Strynar, 2019; Stoiber et al., 2020; Luo et al., 2020; Zheng et al., 2021; Ruyle et al., 2021). The output of hierarchical clustering is a labeled data set, where each sample is classified as part of a group (cluster) of similar PFAS mixture signatures. The collective signatures represented by each cluster can then be used as a forensic fingerprint. Based on the expected composition of PFAS released by the site, these fingerprints can be utilized to differentiate between PFAS attributed to the site and PFAS that is not site related.

2.3 Drinking-Water Data Set Evaluated

The data set used for the analysis is provided in Appendix A and included the following:

- Third quarter 2023 granular activated carbon (GAC) system prior to treatment (PT) PFAS results for drinking water sources in Ohio and West Virginia analyzed for 40 PFAS via EPA Method 1633.
- PFAS results for new drinking water sources in Ohio and West Virginia sampled after April 22, 2022 through March 27, 2024, which were analyzed for 18 PFAS via EPA Method 537.1.

2.4 Data Preprocessing

Treatments performed on the data prior to analysis included censoring of non-detects, removal of field duplicates, feature selection by PFAS analyte, observation selection using a lower bound of three PFAS detections per sample, and data transformation, as described in detail below.

Results reported as non-detect are considered to be left-censored data, limited by the sensitivity of the analytical procedures and their ability to quantify low concentrations. It is not appropriate for multivariate statistical analysis to impute these censored concentrations at a value of zero. On the contrary, it is beneficial to represent the variability that would occur on the interval of zero to the limit of the method's technical capability. Because method detection limit data can vary drastically depending on factors such as dilution factors, the lower limit of sensitivity for the purposes of this analysis was considered to be the lowest reported detected concentration for each analyte. Therefore, to estimate potential “true” concentrations below that limit in non-detect observations, a sample of 100 replicates was drawn from a uniform random distribution on the interval of zero to the analyte’s minimum detected concentration, and the mean of that sample was imputed as the observation’s value. In effect, this approximates half of the lower sensitivity limit while preserving the random variability that is expected in such observations, preventing undue weight being placed on a single repeated censored value (as is the case in simple imputation of zero or a multiple of the reporting limit) in data visualizations, pattern recognition analyses, and regression (Brereton, 2009).

A subset of the initial drinking water data set was created by careful, unbiased selection of observations (samples) and features (PFAS analytes). Feature selection was performed on the combined PFAS concentration features, which initially represented 40 PFAS compounds. The compounds were selected based on their detection frequency,

which ensures that only compounds with sufficiently defined concentrations were used in the analysis. Compounds with a detection frequency greater than 20% were retained. This included seven compounds: PFOA, perfluorobutane sulfonic acid (PFBS), PFHpA, perfluorohexane sulfonic acid (PFHxS), PFHxA, perfluorooctane sulfonic acid (PFOS), and HFPO-DA.

In support of this feature selection, these seven compounds were found to include the highest concentrations of PFAS as well. After feature selection, observations were selected that had at least three PFAS detections in order to provide enough information and variation for pattern recognition. Total PFAS concentrations were assessed during this data selection step to ensure that observations with fewer than three detections did not exhibit uncharacteristically high concentrations in their limited detections. This was done to identify whether there is a pattern of significant PFAS impact associated with just one or two analytes, as opposed to multivariate mixtures, which would have necessitated separate consideration. The final drinking water data set selected for the statistical data analysis contained a total of 160 observations. Prior to subjecting data to PCA and hierarchical clustering, various forms of data preprocessing such as autoscaling, logarithmic transformation, and compositional log ratios were explored. Ultimately, the most applicable pattern recognition results were obtained by transforming the PFAS concentration data into compositional ratios representing each analyte's contribution to the total for each sample, and then transforming that data into centered log ratios (CLR) prior to scaling and centering using z-scores (Brereton, 2009; Miller et al., 2018; Varmuza and Filzmoser, 2009).

3.0 Results

3.1 Initial Data Observations

Prior to statistical analysis, initial observations were made of the data set. The overall center and spread of the PFAS concentrations of the selected analytes are shown in Table 3-1. The highest concentration of PFAS was seen in PFOA at a maximum concentration of 4.40 micrograms per liter (µg/L), with an average concentration of 0.479 µg/L. The second highest PFAS was seen in PFOS at a maximum of 2.70 µg/L; however, PFOS had a much lower average concentration at 0.0186 µg/L. A similar observation was made for PFHxS, which had a maximum concentration of 1.00 µg/L but an average concentration of 0.00818 µg/L. The maximum concentrations of the other four PFAS compounds were lower, ranging from 0.120 µg/L (PFHpA) to 0.210 µg/L (HFPO-DA). The full cluster-labeled data set used for the forensic analysis can be found in Appendix A.

3.2 Isolated PFAS Mixture Signature Groups

Four clusters were selected to differentiate the drinking water PFAS signatures. A statistical estimate for the best number of clusters (k) was formed using the common tests of the elbow method and average silhouette scores. These metrics are calculated for each iteration of k, the total number of clusters, in order to define a range where statistical differentiation of clusters is high, meaning that there is a relatively high average silhouette score, and the total number of clusters is found after the inflection point on the curve of the elbow method plot. On Figure 3-1, the elbow method (left) showed most significant inflection in the range of 4 to 6 clusters, and the silhouette scores (right) showed the highest score at k=2, and relatively stable clusters at divisions greater than 3 clusters. Therefore, the optimal k value was determined to be the range of clusters determined by further tests that simultaneously maximized the average number of samples per cluster and captured the PFAS forensic metrics discussed in the report, such as good separation between clusters in the PCA biplot, shown in Figure 3-2 and a visual examination of the dendrogram shown in Figure 3-3. The dendrogram shows the hierarchy formed by the groups and how they are related to each other as the number of clusters increases for each incremental branch split on the diagram. Clusters with connections that are located higher on the dendrogram are less similar than those with connections closer to the x-axis. Therefore, as the number of clusters extracted from the data increases, the PFAS mixture similarity within the clusters increases.

The average PFAS compositions and concentrations for each cluster are shown as bar plots on Figure 3-4 and presented in Table 3-2. Cluster 1 was the smallest cluster and the most unique compared to the other 3. With 18 samples, Cluster 1 was the only cluster dominated by PFOS at 48.0% of the cluster's composition. Cluster 1 also had high contributions of the other two sulfonate compounds when compared to the other clusters. PFHxS made up 18.5% of the cluster's make-up and PFBS made up 3.91%. In comparison, Clusters 2, 3, and 4 each showed contributions of PFOS and PFHxS at less than 1%. Additionally, the PFBS contribution to these clusters was also smaller. PFBS in cluster 2 was at 1.39%, and Clusters 3 and 4 were both less than 1%. Cluster 1 was only 22.7% PFOA, whereas Clusters 2, 3, and 4 were all dominated by PFOA at 91.5%, 93.88%, and 90.2%, respectively.

Clusters 2, 3, and 4 were similar with regards to PFOA but had some differences in the compositional make-up of the minor compounds. Cluster 2 was the largest cluster

overall, with 73 samples. PFHpA and PFHxA made up 2.55% and 2.22% of the cluster, respectively, while HFPO-DA made up 1.13%. Compared to the other clusters, Cluster 3 had the highest percent composition of HFPO-DA at 2.31% and the lowest percent compositions of PFHpA (2.12%) and PFHxA (1.56%). On the other hand, Cluster 4 had higher percentages of PFHpA (4.43%) and PFHxA (4.43%) but lower percentages of HFPO-DA (0.72%). Although not similar in major composition, Cluster 1 also had some minor impacts from PFHpA and PFHxA at 2.51% and 4.14%, respectively. Overall, Cluster 1 is the most unique cluster, with Clusters 2, 3, and 4 showing similarities with some differences in the minor compounds.

4.0 Forensic Interpretation

This section focuses on the results of chemical forensics conducted with the analytical data obtained to date. In general, samples with the highest PFAS concentrations were dominated by PFOA with minor impacts from PFHpA, PFHxA, and HFPO-DA, which is consistent with expected fingerprint(s) of site-related PFAS.

In this evaluation, three clusters, Clusters 2, 3, and 4, were identified to be primarily site-related. As shown in Figure 4-1, these three clusters were also spatially closest to the site, with the furthest points to the northeast and northwest, which is consistent with the primary directions of wind flow at the site. In contrast, most of the samples in Cluster 1 were far from the site, with some located to the south. Cluster 1 also showed a more unique fingerprint compared to the others, with PFOS as the dominant constituent and an overall higher presence of PFHxS. Additionally, Figure 4-2 shows that total PFAS concentration in Clusters 2, 3, and 4 are decreasing with increasing distance from the site, whereas Cluster 1 shows low concentrations for samples closest to the site and one high concentration for a sample that is greater than 25 miles away. This suggests that the principal sources of Cluster 1 are not site related, unlike the other clusters.

To view the similarities and differences between the clusters and within each cluster, pie charts of the PFAS mixtures and key diagnostic groups can be overlaid on a map. Figure 4-3 and Figure 4-4 show the PFAS mixture pie charts on a map. Figure 4-3 shows the distribution of seven PFAS evaluated for each sample, whereas Figure 4-4 excludes PFOA so that the differences in the relative amounts of the minor constituents are more obvious. In Cluster 1, there are three samples to the south of the site with a significant amount of non-site related sulfonate compounds; however, most of the other samples in the cluster have a significant amount of PFOA as seen in Figure 4-3.

Spatially, the individual PFAS mixtures are complex. When PFOA is not shown, as is seen in Figure 4-4, most of the minor constituents in the samples in Cluster 1 are the sulfonate compounds: PFOS, PFHxS, and PFBS, which support a non-site related source. Moreover, Figure 4-4 shows that in Cluster 2, most of the samples' minor constituents are the site-related compounds. However, there appears to be some impacts from PFBS throughout the cluster. Cluster 3 is the closest cluster to the site, with all its samples falling within 10 miles of the Site. This cluster also has virtually no impacts from the sulfonate compounds and has the highest impacts from HFPO-DA compared to the other clusters. This is likely due to the replacement of PFOA by HFPO-DA since 2013 and reduced emissions as a result of abatement systems put in place, giving HFPO-DA less time to travel. Cluster 4 is more widespread, with samples from about one mile from the site to 18 miles from the site, and it appears to be more representative of the older site-related PFAS mixture, given the low presence of HFPO-DA and the higher presence of PFHpA and PFHxA.

5.0 Conclusions

In this report, AECOM describes the approach taken to identify fingerprints in PFAS compositions of drinking water samples to differentiate sources of PFAS in the area.

During the statistical analysis, unsupervised pattern recognition via PCA and hierarchical clustering provided groups of similar chemical signatures for further exploration and identification of specific source fingerprints based on the full chemical, statistical, and spatial profile. In doing so, four clusters were identified.

The PFAS fingerprint in Cluster 3 is consistent with the site-related PFAS since the switch from PFOA to HFPO-DA, and the PFAS fingerprint in Cluster 4 is consistent with the older site-related PFAS, before the switch to HFPO-DA. Cluster 2 is also consistent with the older site PFAS mixture; however, there is some mixing in Cluster 2 with non-site related PFAS, primarily PFBS. The PFAS fingerprint in Cluster 1 appears to be principally non-site related, as evidenced by the higher levels of the sulfonate compounds, although there does appear to be some mixing in certain samples of Cluster 1, as demonstrated by the high presence of PFOA. The mixing of sulfonate compounds in Clusters 1 and 2 indicate the presence of a low-concentration source that is not related to the site.

The results of the statistical forensics data analysis support the initial observations made from the dot map evaluation, which indicated that there is a site-related pattern observable in the data set, but that there are also localized hot spots in the data set that are consistent with a non-site related source.

1. Regulatory Location ID = a number assigned to each sampling location
2. DistWW_mi = the calculated distance from a center point on the Washington Works Plant to the sampling location in miles
3. PFAS = per- and polyfluoroalkyl substances [PFOS = perfluorooctane sulfonic acid , PFOA = perfluorooctanoic acid, PFHxA = perfluorohexanoic acid , PFHxS = perfluorohexane sulfonic acid , PFHpA = perfluoroheptanoic acid, PFBS = perfluorobutane sulfonic acid, HFPO-DA = hexafluoropropylene oxide dimer acid (also commonly referred to as GenX)]
4. per_ = composition of PFAS compound relative to the total PFAS. See Section 2.0 of the Washington Works PFAS Statistical Forensics Analysis report (dated July 2024) for a detailed explanation.
5. X. = centered log ratio transformation of the PFAS compositional data. See Section 2.0 of the Washington Works PFAS Statistical Forensics Analysis report (dated July 2024) for a detailed explanation.
6. Cluster = See Section 2.0 of the *Washington Works PFAS Statistical Forensics Analysis* report (dated July 2024) for a detailed explanation.
