EXECUTIVE SUMMARY

On behalf of Philadelphia Coke, Co., Inc., Arcadis U.S. Inc. (Arcadis) has prepared this Remedial Investigation (RI) Report and Cleanup Plan for the Former Philadelphia Coke Plant location in the Bridesburg Borough of Philadelphia, Pennsylvania (the Site). The Site is located at 4501 Richmond Street between Orthodox Street and Buckius Street and is adjacent to the Delaware River. The Site is approximately 63 acres in size and is currently unoccupied. The Site is overgrown with vegetation and only remnants of the former operating structures, foundations, and concrete pads remain. All former structures at the Site have been demolished to ground level. A mix of residential, industrial, and commercial uses surrounds the Site. Plans are currently being prepared for Site redevelopment and use for commercial warehousing (see Exhibit 1).

Site operations concluded in 1989. Resource Conservation and Recovery Act (RCRA) Closure actions were conducted at the plant in the late 1980s to address source area contamination located at specific RCRA Hazardous Waste Management Units. Extensive soil remediation was performed as part of the RCRA closure with nearly 39,000 tons of soil transported offsite for treatment/disposal. In addition, bioremediation was performed in a former fuel blending area and former underground storage tanks and residual oil in piping removed. Periodic (typically quarterly) groundwater monitoring began in April 1985 to evaluate groundwater conditions at the Site. The Certificate of Completion for RCRA Site Closure was issued by the United States Environmental Protection Agency (EPA) on December 28, 1994 (WCC 1994). Following receipt of the Certificate of Completion, PCC continued to monitor groundwater quarterly, until the Pennsylvania Department of Environmental Protection (PADEP) authorized termination of the groundwater monitoring program in a July 26, 1999 letter. No outstanding closure responsibilities associated with the RCRA Corrective Action remain. The Site has not been occupied since 1991. Other than the Site investigations discussed herein and site investigations conducted for Site redevelopment (under a Site-specific health and safety plan), no other Site activities or operations besides routine mowing and maintenance of the perimeter chain-link fence have been conducted since the RCRA Closure.

RI Activities and Results

The RI was undertaken to assess the nature and extent of residual Site-related environmental impacts, if any, and evaluate the risks posed to human health and the environment by those impacts. The RI was performed in two major phases: (1) the Initial RI activities from 2003 through 2006; and (2) the Supplemental RI activities from 2018 and 2019. When combined, work activities performed for the RI consisted of the following:

- Excavating 197 test pits and collecting soil samples from 145 test pits.
- Installing 179 soil borings and collecting soil samples from 150 soil borings.
- Installing and sampling 33 shallow groundwater monitoring wells, 13 deep groundwater monitoring wells, and 7 hydropunch borings.
- Analyzing approximately 540 soil samples and 112 groundwater samples for volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), inorganics, cyanide, pesticides, and/or polychlorinated biphenyls (PCBs).

- Collecting 21 soil gas samples and one ambient air sample for VOCs (via Method TO-15), Naphthalene (via GC/MS in the full scan mode) methane, and fixed gases (via American Society Testing and Materials Method D-1946).
- Performing sediment probing in the Delaware River and a visual reconnaissance of the shoreline for sheens, tar-like material, elevated photoionization detector readings, or other observable indications of Site-related impacts.

The results of the RI provide adequate coverage across the Site to: (1) identify and delineate residual environmental conditions; (2) support a Risk Assessment Report; (3) develop a Cleanup Plan; and (4) support Site redevelopment.

Based on observations of soil samples recovered from soil borings across the Site, there are three hydrogeological units above weathered metamorphic schist bedrock. Nearest the ground surface is a layer of man-made fill materials that generally meets the description of historic fill as defined in Pennsylvania Department of Environmental Protection's Management of Fill Policy (Document #258-2182-773) dated January 1, 2020. A confining unit of silt and clay material underlies the fill materials and underneath that confining unit is a sand and gravel unit. Groundwater at the Site is separated into a shallow and deep zone by the silt and clay layer. Shallow groundwater is located within the historic fill and mounds in the central/southern portion of the Site and flows radially outward from the mound. The shallow groundwater zone was formed by the historical placement of fill above native surface soils. Due to the presence and characteristics of the historic fill, it is not suitable for use. Deep groundwater is located within the sand and gravel unit flows eastward toward the Delaware River. Groundwater does not appear to be tidally influenced or affected by the presence of the municipal Upper Delaware Connecting Sewer (reportedly 11-foot-3-inch to 12-foot-3-inch diameter) that bisects the western portion of the Site, other than a limited tidal influence on deep groundwater (generally less than 1 foot) nearest to the Delaware River. The Upper Delaware Collecting Sewer conveys regional storm water deep beneath the Site; however, it does not collect any storm water from the Site itself.

Soil analytical results and visual impacts (e.g., viscous tar, oil-like material, and solidified tar) indicate the presence of localized impacts in the center of the Site and at isolated locations on the remainder of the Site. In general, visual impacts are associated with the former process piping and foundations, except for impacts found in the vicinity of a former aboveground storage tank farm (east of Former Byproducts Building). Visual impacts are limited to the fill layer or the top few feet of the silt and clay layer and were not observed to have penetrated the confining unit. Based on the observed variations between original and revisited sampling locations from the Initial RI to the Supplemental RI, viscous tar and oil-like material appear to be limited to isolated pockets and not reproduceable from the original sampling event (i.e., not as extensive and/or contiguous as the Initial RI indicates). Additionally, groundwater analytical results do not indicate the presence of source material onsite.

Areas of the Site exhibiting elevated concentrations of chemical constituents and visual impacts have been delineated for purposes of cleanup plan development. Laboratory analytical results of soil, groundwater, and soil gas samples are summarized below:

- Surface soil was found to contain polycyclic aromatic hydrocarbons (PAHs), arsenic, and lead at concentrations exceeding non-residential direct contact medium-specific concentrations (MSCs). PAHs, arsenic, and lead are commonly associated with urban/historic fill, which is encountered

throughout the Site. The PAHs identified at concentrations exceeding MSCs consist of 2-methyl-naphthalene, benz(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, chrysene, dibenz(a,h)anthracene, dibenzofuran, and naphthalene at isolated locations in the center of the Site and at two locations near the Site perimeter (i.e., PCTP-66 and S-151). Arsenic was identified at concentrations above MSCs at limited locations. Lead at concentrations not typical of urban fill was identified in surface soil samples from the Fuel Blending Area and two locations in the center of the Site. No pesticides or PCBs were identified in surface soil at concentrations exceeding non-residential, direct contact or soil-to-groundwater MSCs. However, benzene, several SVOCs, and metals were identified in surface soil at concentrations exceeding the non-residential soil-to-groundwater MSCs.

- Subsurface soil was found to contain a small subset of SVOCs, consisting of 1,1-biphenyl, 2-methyl-naphthalene, and naphthalene, at concentrations exceeding non-residential direct contact MSCs. These SVOCs were identified primarily in the center of the Site where viscous tar and oil-like materials were observed. No VOCs, inorganics, PCBs, pesticides, or other SVOCs were identified in subsurface soil at concentrations exceeding the non-residential direct contact MSCs. Several VOCs, SVOCs, and metals (primarily benzene, PAHs, lead and arsenic) were identified in subsurface soil at concentrations exceeding the non-residential soil-to-groundwater MSCs.
- Groundwater impacts are generally limited to areas where viscous tar and oil-like materials were observed. Groundwater monitoring wells installed downgradient of these areas indicate that Site-related groundwater impacts do not extend offsite. Outside of these isolated areas, groundwater is unimpacted by former Site operations; existing groundwater conditions are typical of groundwater in urban/historic fill. Groundwater impacts are primarily within the shallow zone. The underlying (deep) aquifer is relatively unimpacted.
- When compared to applicable non-residential vapor intrusion (VI) standards, soil and groundwater analytical results indicate the potential for soil related VI in future buildings in certain areas onsite in the absence of remediation or mitigation. However, soil gas analytical results did not exceed the sub-slab VI screening values, indicating that the VI potential may be over-predicted by the soil and groundwater analytical results.

The COCs related to Site operations include: several PAHs and lead in surface soil; several VOCs, SVOCs, and inorganics in subsurface soil; and benzene, several SVOCs, and inorganics in groundwater. Site-related impacts in soil and groundwater have been delineated for purposes of developing a cleanup plan.

From a risk perspective, there are currently no complete exposure pathways for human receptors. Soil exposure is controlled by Site use (i.e., the Site is vacant), Site fencing, vegetation, and the presence of non-permeable surface covers (e.g., old asphalt parking lots). No current exposure pathways are complete for groundwater or soil vapor.

Future use of the Site will be restricted to non-residential by use of an environmental covenant. Potentially complete future exposure pathways could exist via soil, groundwater, and VI. However, groundwater is not used or anticipated to be used for potable purposes at the Site and in the surrounding area. Pathway elimination strategies will be integrated with the Site development plans to mitigate

potentially complete future exposure pathways to ensure protection of human health and the environment.

Potentially complete exposure pathways for ecological receptors are direct contact and incidental ingestion of surface soil, and ingestion of contaminated prey. Direct contact to the historic fill is most likely to occur from burrowing mammals or small mammals that may incidentally ingest soil as part of their dietary exposure to prey items in the existing leaf litter. Larger wildlife (e.g., deer) may forage on the vegetation present, but would have limited dietary exposure to surface soil. Similar to the means for addressing human exposure, capping and/or limited removal of COCs as part of a protective cleanup plan will effectively eliminate potential ecological exposure to surface soil at the Site.

Cleanup Plan Summary

Based on the RI results, Philadelphia Coke Co., Inc. proposes to pursue a release of liability under the Act 2 Site-Specific Standard via a “pathway elimination” cleanup approach. Potentially complete future exposure pathways will be eliminated using engineering and institutional controls. The Cleanup Plan has been developed and presents the proposed methods to prevent further migration and eliminate potentially complete future exposure pathways. Although source material (e.g., non-aqueous phase liquid), was not encountered in the RI, the Cleanup Plan also includes provisions for addressing source material if encountered in the future. The remedial strategies presented in the Cleanup Plan will be integrated with Site development plans, once finalized. Conceptual development plans are currently being prepared and include commercial warehouse buildings, parking lots, access roads, driveways, and various landscape features, as shown in Exhibit 1.

The proposed remediation will achieve the Site cleanup objectives to protect human health by mitigating identified future exposure pathways with soils and groundwater impacted by applicable Site COCs. The Cleanup Plan:

- Provides methods to achieve pathway elimination for soils using engineering controls (i.e., capping of soils with structures, roadways, parking lots, and landscaping).
- Provides methods to achieve pathway elimination for vapor intrusion using engineering controls (i.e., use of a vapor barrier specifically designed, manufactured, and installed for use in VOC mitigation) within areas of potential VI concern.
- Outlines procedures and plans to allow for safe execution of future Site remediation and/or redevelopment activities.
- Specifies institutional controls to be implemented (i.e., deed notice, restrictions, or other appropriate vehicles).
- Outlines a Post-Remediation Care Plan.

The remedial goals for soil will be to allow historic fill and impacted soils to remain in place or be reused onsite (e.g., as subsurface fill), to the extent possible, while mitigating potentially complete exposure pathways via engineering and institutional controls.

The engineering controls will consist of: (1) caps(s) overlaying areas where potential pathways exist for direct contact exposure; and (2) VI mitigation system(s) within areas of potential VI concern identified by initial VI screening (as specified within this report) or a building-specific VI risk assessment addressing

any potential future development. The proposed cap may include concrete floor slabs/foundations for new buildings; asphalt pavement and/or concrete for driveways, parking areas, and sidewalks; and/or 2-feet of clean soil (e.g., in landscaped areas) to eliminate potential direct contact exposure scenarios. With the exception of the existing railroad, the entire Site will be capped by various methods to meet the Site-Specific Standard via “pathway elimination”. Asphalt pavement and buildings will significantly reduce and limit infiltration across much of the Site; stormwater runoff will be collected and conveyed offsite to the river.

Engineering controls (e.g., vapor barriers) will be used, where appropriate, to mitigate the potential VI pathway for COCs. Although not needed in certain areas of the Site (e.g., the western portion of the Site along Richmond Street), the current redevelopment plans are to install VI mitigation systems for all proposed occupied structures onsite. Alternatively, the Site-Specific Standard may also be pursued through completion of a cumulative VI risk assessment and/or additional soil-gas sampling to demonstrate that VI mitigation is not needed.

An environmental covenant with deed restrictions/notifications will be incorporated as an institutional control. The Site will be restricted to non-residential use to limit potential future receptors, and groundwater use will be prohibited to eliminate potential future groundwater exposure pathways. In addition, institutional controls will stipulate inspection, periodic maintenance/repair activities, and reporting requirements for soil caps and VI mitigation systems, as appropriate. Following implementation of the remedy included in the approved Cleanup Plan, a Final Report will be prepared in accordance with Act 2 requirements to obtain a release of environmental liability for the Site.

1 INTRODUCTION

On behalf of Philadelphia Coke Co., Inc. (PCC), Arcadis U.S. Inc (Arcadis) has prepared this Remedial Investigation (RI) Report and Cleanup Plan for the Former Philadelphia Coke Plant location in the Bridesburg borough of Philadelphia, Pennsylvania (the Site). This RI Report and Cleanup Plan was prepared in accordance with Pennsylvania's Land Recycling Program Technical Guidance Manual updated on March 27, 2021, the medium-specific concentrations (MSCs) updated on November 20, 2021, the Land Recycling and Environmental Remediation Standards Act (Act 2), and its enabling regulations, 25 PA Code, Chapter 250. This report provides:

- A summary of the RI activities performed to delineate the nature and extent of Site-related chemical constituents (constituents of concern [COCs]) at the Site.
- An Ecological Screening to evaluate potential exposure of environmental receptors at the Site.
- An assessment of potentially complete exposure pathways (current and future) associated with the COCs.
- A Cleanup Plan for affected media at the Site to mitigate the potentially complete future exposure pathways based on identified conditions.
- A Post-Remediation Care Plan (PRCP) to ensure that no future exposure pathways to remaining COCs at the Site exist.

A Notice of Intent to Remediate (NIR) was submitted to Pennsylvania Department of Environmental Protection (PADEP) on November 19, 2018 (Appendix A). The NIR stated that PCC is seeking a release of liability under the Act 2 Site-Specific Standard.

The objective of the Act 2 Site-Specific Standard is to develop and evaluate detailed site information to provide a protective cleanup standard unique to that site. The Site-Specific Standard is a risk management approach (PADEP 2021). For the purposes of this Site, the proposed Site-Specific Standard will generally be the "pathway-elimination" approach, which means that potentially completed future exposure pathways will be eliminated using engineering and institutional controls. Engineering controls that may be implemented at the Site include covering impacted soils with asphalt/concrete paving, building structures and/or a minimum 2-foot thick clean soil covers to prevent direct contact exposure to Site COCs and installation of barriers or vapor mitigation systems to mitigate potential vapor intrusion (VI) into future buildings constructed on the property. Institutional controls that could be considered include deed restrictions/environmental covenants: (1) prohibiting use of groundwater at the Site; (2) limiting future soil disturbance in areas with engineering controls; (3) limiting future development in specific areas of the Site; and/or (4) requiring a Soil Management Plan that stipulates inspection, periodic maintenance/repair activities, and reporting requirements for engineering controls, as appropriate (PADEP 2021).

The information presented in this RI Report and Cleanup Plan reflects, in part, the information provided in a March 5, 2019 Kick-Off Meeting and March 8, 2021 Project Update Meeting with PADEP and the United States Environmental Protection Agency (EPA). The RICP has been revised based on December 16, 2021 and January 3, 2022 calls with EPA, a January 14, 2022 PADEP Disapproval Letter (providing

PADEP RICP Comments #1 through #7), and January 31, March 1, March 24, and March 28, 2022 calls with PADEP.

Remedial alternatives based on the future development of the Site as an industrial and/or commercial property are presented in the Cleanup Plan. Remedial strategies presented in the Cleanup Plan will be integrated with Site development plans, once finalized by the purchaser/developer of the property. Conceptual development plans are currently being prepared and include commercial warehouse buildings, parking lots, access roads, driveways, and various landscape features, as shown in Exhibit 1. The Cleanup Plan presents the general approach and typical methods that will be used to mitigate potentially complete exposure pathways in accordance with Act 2.

1.1 Report Organization

The organization of this RI Report and Cleanup Plan is presented below.

Table 1-1: Report Organization

Section		Purpose
Section 1	Introduction	Provides information relevant to the development of this report and the objectives of this report.
Section 2	Site Information	Presents a description of the Site setting, production history, and historical investigations and remediation.
Section 3	Remedial Investigation	Describes the field investigation to evaluate the extent of former Site-related environmental impacts and the findings of that investigation.
Section 4	Groundwater Models	Evaluates the extent of constituent migration in groundwater in the absence of any remedial activities.
Section 5	Conceptual Site Model	Evaluates the risks posed to human health and the environment by Site-related impacts. This section summarizes the potential current and future migration and exposure pathways for the identified impacts.
Section 6	Ecological Screening	Evaluates the potential exposure of environmental receptors at the Site.
Section 7	Public Benefits to Remediation and Reuse	Presents a summary of public benefits of the redevelopment and reuse of the property. Industrial and commercial development benefits are evaluated.
Section 8	Remedial Investigation Conclusions	Presents a summary of the RI and the Site-related environmental impacts.

Section		Purpose
Section 9	Cleanup Plan	Presents the proposed cleanup objective and process, project personnel, selected remedial standards, the public participation, the cleanup actions to attain the remedial standards, and the post-remediation activities.
Section 10	Summary and Conclusions	Presents a summary of the proposed cleanup actions to address the impacts.
Section 11	Signatures	Provides a signature of the Site owner's representative.
Section 12	References	Presents a list of the references cited in the RI Report and Cleanup Plan.

1.2 Objectives

The overall objective of this RI Report is to define the nature and extent of residual Site-related environmental impacts, if any, and evaluate the risks posed to human health and the environment by those impacts. The RI identifies the potential human exposure pathways and environmental risks in sufficient detail to support the proposed Site remedial approach and non-residential use redevelopment scenario. The RI objectives were met by filling data gaps from previous investigations and cleanup activities.

The RI results are used to develop a conceptual Cleanup Plan for the property. The Cleanup Plan has been developed to meet the Act 2 Site-Specific Standard. Based on the RI findings, the cleanup objective for the Site is to protect human health by mitigating identified exposure pathways with soil and groundwater impacted by select volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), and inorganics in locations where COC concentrations exceed the respective non-residential MSCs.

Following implementation of the remedial alternatives included in the approved Cleanup Plan, a Final Report will be prepared in accordance with Act 2 requirements to obtain a release of environmental liability for the Site.

2 SITE INFORMATION

This section presents relevant background information used to develop the RI scope. The Site location and history are described below, followed by a summary of previous investigations and remediation activities.

2.1 Location and Description

The Site is located on 4501 Richmond Street between Orthodox Street and Buckius Street in the Bridesburg borough of Philadelphia, Pennsylvania. The Site is bounded to the west by Richmond Street, Lefevre Street, and Garden Street; to the north by Buckius Street; to the south by Orthodox Street; and to the east by the Delaware River[1]. The Site is approximately 63 acres in size and is currently unoccupied. The Site is overgrown with vegetation and only remnants of the former operating structures, foundations, and concrete pads remain. All former structures at the Site have been demolished to ground level, and the Site is currently vacant and unoccupied. The Site is secured by a perimeter chain-link fence that is routinely inspected and repaired, as needed. The Site will remain unoccupied until redevelopment. The Site location is shown on Figure 1.

The Delaware River is the primary hydrologic feature within the region. The river is classified by PADEP as a warm-water fish designated use river/stream. The Delaware River flows north to south to the Atlantic Ocean at the Delaware Bay. Surface flow onsite drains southeast into the Delaware River. A watershed map of the Lower Delaware River Watershed is included as Figure 2.

A large municipal storm sewer identified as the “Upper Delaware Collecting Sewer” (reportedly 11-foot-3-inch to 12-foot-3-inch diameter) extends across the western portion of the Site, from the intersection of Bath Street with Orthodox Street to the south and Buckius Street to the north but does not collect or convey stormwater from the Site. The invert elevation of this sewer was estimated to be at least 29 feet below ground surface (bgs; equivalent to 15.79 feet below mean sea level). An active utility corridor and the inactive Philadelphia Beltway Railroad extend through the eastern portion of the Site.

A mix of residential, industrial, and commercial properties surround the Site. To the west (along Richmond Street) is a mix of commercial enterprises and residential housing. To the south (along Orthodox Street) and to the north (along Buckius Street) are commercial and industrial properties. To the east is the Delaware River.

Ground surface elevations vary throughout the property. The ground surface is lowest near the bulkhead at the Delaware River (at elevations ranging from 5-6.5 feet above mean sea level [AMSL]) and then rises slightly to the west to approximately 8-9 feet AMSL near the utility corridor. West of the utility corridor, the ground surface elevation changes significantly, advancing into the upland areas of the Site in a westerly and northerly direction towards the Site center. The highest ground surface is near former tar holders in the approximate center of the Site, and in the southeast corner of the Site. The ground surface elevations west of the utility corridor range from approximately 10 to 21 feet above AMSL.

[1] For purposes of this report, north (i.e., plant north) is perpendicular to Buckius Street (55 degrees each of the true north shown on the Site figures.

2.2 History

The Site was developed in the mid-1920s to provide manufactured gas to the City of Philadelphia (the City). Facility operations from January 1929 to May 1982 focused on the production of metallurgical coke by the Philadelphia Coke Co., Inc. Principal processes included coal and coke storage, coke production, tar storage, by-product operations, and iron oxide storage. The Site also included an iron oxide waste area and tar plain area. A fuel oil blending facility operated on the eastern 2.5 acres of the Site from approximately 1969 through 1989 by Patterson Oil Co. and Eastern Gas Co.

Coal and Coke Storage Areas were located in the northern portion of the Site. The main Coking Operations Area was in the center of the Site and consisted of the coke ovens, the by-products building, tar storage, and oxide boxes. The facility had two aboveground storage tanks (ASTs) that were used to store product coal tar with estimated capacities of 500,000 and 1,000,000 gallons. Additionally, there was one tank farm with concrete secondary containment for four ASTs and a second tank farm with two fuel oil tanks surrounded with an earthen berm (Woodward-Clyde Consultants [WCC] 1992a). The Main Operations Area is where Resource Conservation and Recovery Act (RCRA) closure activities were implemented and included the Spent Iron Oxide Storage and Tar Plain Areas. The Fuel Blending Area was in the eastern portion of the Site and consisted mainly of aboveground storage and below ground piping. The overall layout of the Former Philadelphia Coke Plant is shown on Figure 3. Historical aerial photographs, Sanborn maps, and other Site plans, including a generalized process flow diagram, are included as Electronic Attachment 1.

The facility carbonized coal in coke ovens. Bituminous coal and limited amounts of anthracite coal were used as raw materials to make metallurgical coke. When combined with limestone and iron ore at high temperatures, metallurgical coke is used to form iron and steel. Metallurgical coke is both fuel and a reactant essential for steelmaking.

During its active years, the facility produced upwards of 220,000 tons of metallurgical coke annually. The facility formerly operated as a large quantity generator of hazardous waste under EPA number PAD000427906. The facility also operated under a National Pollutant Discharge Elimination permit number PAD0011401.

The primary waste materials (residual tar, spent iron oxide, etc.) generated by the coal carbonization process resulted from coal gas cleaning and cooling systems. During the coal carbonization process and subsequent gas cleaning and cooling operations, various heavy hydrocarbons were generated and combined with fine coal or coke solids in the gas stream. This combination then settled in the tar decanters, which principally functioned as tar/water separators. Periodically, the settled mixture in the decanters (decanter tank sludge), as well as waste material in the iron oxide waste storage area, was removed for offsite disposal. The facility manufactured and generated several types of products and wastes. Former Site operations and waste generated is summarized in the Engineer's and Owner's Certification of Closure for Waste Management Units, prepared by WCC in December 1992 (RCRA Closure Report; WCC 1992b) which is included in Electronic Attachment 2.

In the early days of plant operation, discharge to surface water from the Site occurred through a single outfall into the Delaware River (Outfall 001). On March 13, 1951, the Philadelphia Coke Company was issued a discharge permit from the Pennsylvania Department of Health. While no documentation was identified regarding the installation of the oil skimmer leading to Outfall 001, it is assumed that it was installed in the early 1950s. In 1975, a substantial portion of the plant's process water was diverted to the

City's sanitary sewer system on Orthodox St. According to a June 28, 1982 letter, Outfall 001 was plugged following the end of Site operations.

The former Fuel Oil Blending Area supported a process whereby Number 2 and Number 6 fuel oils were brought to the Site by barge and off-loaded. The oil was stored and blended prior to local distribution by tanker truck.

All above-ground structures have been demolished to ground level.

2.3 Historical Investigations and Cleanups

Prior to the RI, various investigations were performed at the Site from the mid-1980s through 2001. The initial investigations were conducted in conjunction with Site closure activities under the federal RCRA program. The results of these investigations are summarized in the RCRA Closure Report (WCC 1992b; Electronic Attachment 2). The RCRA Closure actions conducted at the plant in the late 1980s addressed source area contamination located at specific RCRA Hazardous Waste Management Units. A series of limited investigations of the Fuel Blending Area were also conducted from 1988 to 1993 and in 2001.

As part of these historical investigations, cleanup activities were performed. Approximately 39,000 tons of material were transported for offsite treatment and disposal. A timeline of historical cleanup activities is provided in the table below, and a discussion of these investigations and cleanups is provided in the following paragraphs.

Table 2-1: Historical Cleanups

Year	Cleanup Description
1982-1988	Removed RCRA waste management units
1988	Removed approximately 9,370 tons of soil impacted with decanter tank tar sludge and spent iron oxide
1988-1993	Removed approximately 29,400 tons of soil impacted with coke breeze, paving material, and coal tar
1992-1993	Performed in-situ soil bioremediation in Fuel Blending Area
1991-2001	Removed underground storage tanks (USTs) and residual oil from pipe segments

2.3.1 RCRA Closure Investigation and Remediation

The initial RCRA investigation was conducted in October 1986. The results indicated that coal tar-related base neutral organic compounds were reported above standards in soil and groundwater in the former operational areas.

2.3.1.1 Historical Groundwater Evaluation

Six onsite shallow groundwater monitoring wells (MW-1 through MW-6[2]) and one deep groundwater monitoring well MW-2D were installed in the central portion of the Site as shown on Figure 4. These wells were generally sampled on a quarterly basis for 14 years, from April 1985 through November 1998, for a total of approximately 40 sampling events. After November 1998, the frequency of groundwater monitoring was decreased to annual monitoring events. In a July 26, 1999 letter, PADEP approved the termination of RCRA groundwater monitoring based on the continuous decreasing trend of constituent concentrations.

The monitoring wells were located in the center of the Site and downgradient from the RCRA soil removal areas. Potentiometric surface maps from the 1980s indicate groundwater flow originating near MW-2 (in the Spent Iron Oxide Storage Area in the center of the Site) and flowing radially west to Garden Street, south to Orthodox Street, and east towards the Delaware River. No monitoring wells were installed north of MW-2 to evaluate groundwater flow to Richmond Street or Buckius Street. Historical potentiometric surface maps are provided in Appendix B.

Groundwater analytical results from the sampling events generally indicated the presence of benzene, toluene, ethylbenzene, and SVOCs. In addition, trichloroethene (TCE), 1,1-dichloroethane, and cis-1,2-dichloroethene were periodically detected at elevated levels onsite. VOC and SVOC impacts were primarily observed at MW-1 (located downgradient from the Former Tar Plain, near the existing PCMW-10 cluster) and MW-2. Benzene, toluene, ethylbenzene, xylene, (BTEX) and EPA's 16 priority pollutant polycyclic aromatic hydrocarbons (PAHs) were not detected in monitoring wells MW-3 or MW-4. MW-3 is located in the eastern half of the Site between the Site center and the former Fuel Blending Area, and MW-4 is located on the western property boundary near the Garden Street properties. Some general water quality parameters (i.e., total base neutral extractables and total VOCs) were slightly elevated in MW-3 and MW-4, but those impacts were attributed to fill materials rather than plant-related activities.

During the final year of groundwater monitoring (1998), benzene and naphthalene remained at concentrations greater than the Maximum Contaminant Levels[3] (5 and 20 micrograms per liter [5 µg/L], respectively) in MW-2R (replacement for well MW-2). In 1998, PAH results (including naphthalene results) were lower than the current applicable groundwater MSCs (i.e., PADEP Non-Residential MSCs for Used Aquifers containing Total dissolved solids [TDS] ≤ 2,500 milligrams per liter [mg/L]).

In the July 26, 1999 letter, PADEP indicated that benzene and naphthalene have not migrated to downgradient wells (MW-1 and MW-3) and that these compounds were not found to be at "any appreciable levels" (according to the PADEP) in MW-2D, MW-4, MW-5, or MW-6 since 1994. Therefore, PADEP indicated that groundwater impacts for these compounds were localized and have been since 1994.

In the July 26, 1999 letter, PADEP also indicated that concentrations of the VOC and SVOC constituents have "significantly decreased from 1985 and 1998". Upon termination of the groundwater program, PADEP acknowledged that concentrations of iron, manganese, specific conductance, potassium, sodium,

[2] Wells identified above as MW-1 through MW-6 were originally identified as W-1 through W-6 in the RCRA closure documentation.
[3] The Maximum Contaminant Levels are from the federal and state Safe Drinking Water Act standards available at the time of the July 26, 1999 letter.

calcium, magnesium, sulfate, and chloride remained elevated. However, PADEP attributed these elevated levels as a natural phenomenon (i.e., related to the fill material). In 1999, PADEP concluded that groundwater impacts at the Site were localized, delineated, and stable and that PCC was no longer subject to any additional groundwater monitoring at that time.

2.3.1.2 RCRA Closure Activities

Closure activities, consisting of excavation and offsite disposal of soil contaminated with decanter tank tar sludge from coking operations (RCRA Waste Code K087), and spent iron oxide (RCRA Waste Code D003) were initiated on July 12, 1988. In total, five RCRA Hazardous Waste Management Units (HWMU) were closed, and 9,370 tons of hazardous waste were removed. Hazardous waste material originated from the tar storage tanks, waste liquor pit, tar plains, tar decanters, and the iron oxide boxes and pile. Hazardous waste removal activities were mostly complete by December 30, 1988.

Following closure of the HWMU, four RCRA Solid Waste Management Units (SWMU) were closed from 1988 to 1992. The SWMUs consisted of a trash pile, clean oxide, wood trays, and process piping throughout the Site. Generated waste consisted of three non-hazardous waste streams: coke breeze, paving material, and coal tar-impacted soil. Approximately 29,400 tons of the coal tar-contaminated soils were removed from the Site and disposed as residual waste at the G.R.O.W.S. landfill facility between February 19 and July 24, 1992. Additionally, approximately 439,800 gallons of groundwater were transported offsite for treatment.

In all closure areas, post-closure sampling demonstrated that the sum of benz(a)anthracene (BaA), benzo(a)pyrene (BaP), benzo(b)fluoranthene (BbF), chrysene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene was less than the 50 milligrams per kilogram (mg/kg) cleanup criteria and none of these constituents were detected at a concentration greater than 15 mg/kg. At the time, these six PAHs were considered to be suspected carcinogens. The results of the post-closure sampling indicated that the cleanup criteria had been achieved.

In 1993, a sixth HWMU was closed. Approximate 20 cubic yards of soil hazardous for benzene were removed from the former seal pot for offsite incineration. The seal pot was in the Former Byproducts Building piping trench. The seal pot was discovered during excavation activities and cleaned in September 1992. Seal pot closure activities were completed on October 19, 1993.

The RCRA excavation areas are shown on Figure 3. The excavation depths were based on visual characterization and varied based on former Site operation locations, as summarized below:

- Decanter Area – excavation depth ranged from 10-13 feet bgs (averaging at 12 feet bgs).
- Oxide Box and Wash Area – excavation depth ranged from 3-10 feet bgs (average 8 feet bgs)
- Tar Plains – excavation depth averaged 11 feet bgs.

The Certificate of Completion for RCRA Site Closure was issued on December 28, 1994 (WCC 1994). No outstanding closure responsibilities associated with the RCRA Corrective Action remain. The Site has not been occupied since the conclusion of the RCRA Site Closure. Other than the Site investigations discussed herein, no other Site activities or operations (besides the routine mowing and maintenance of the perimeter chain-link fence) have been conducted since the RCRA Closure.

2.3.2 Fuel Blending Area Investigation

In 1988, oily residue was observed on surface soils near a former pump house in the Fuel Blending Area. This observation prompted the initiation of a series of limited investigations between 1988 and 1991. Total Petroleum Hydrocarbon (TPH) concentrations ranging from 1,000 to 250,000 mg/kg were reported in various locations within the Fuel Blending Area. The highest concentrations were reported from the unsaturated zone in the fill layer.

Cleanup activities in the Fuel Blending Area were initiated in 1992. These activities included the excavation and disposal of potential fuel oil sources consisting of subsurface piping between the former aboveground tanks and the pump house and oily residues present in the basement of the former pump house. A bioremediation project was conducted for almost two years and reported moderate success in reducing hydrocarbon concentrations in the surface soils (0 to 3 feet bgs), but only limited success with deeper contamination. The project was discontinued in late 1993 and the above-grade facilities were dismantled and removed in early 1998.

In 2001, Miller Environmental Group, Inc. removed oil from the transport pipe that extended from the pier to the fuel oil tanks. No. 2 fuel oil was encountered in the piping and removed for appropriate offsite disposal. During pipe removal, oil was reported floating on the perched groundwater near the western terminus of the pipe segments.

URS Corporation (URS) completed a test pit investigation in 2001 to delineate fuel oil impacts in the Fuel Blending Area observed during the pipe cleaning. A total of 18 test pits were excavated. Based on the observations during the investigation, a relatively thin zone of fuel oil impacts was encountered from 1 and 2 feet above the observed water table to 1 and 2 feet below the water table in the six test pits completed inside the Fuel Oil Blending Area berm. Sheens were observed in an additional five test pits. Impacts were not observed in the test pits completed outside this berm near the Delaware River. The results of the test pit investigation are summarized in a December 13, 2002 URS letter report (Electronic Attachment 3).

2.3.3 Underground Storage Tank Removals

Seven USTs were removed from the Site in July 1991. These USTs were registered with the Pennsylvania Department of Environmental Resources (PADER) at the time of the authorization and assigned Facility Identification No. 51-44990. The UST removals were performed under the oversight of PADER and the City of Philadelphia Department of Licenses and Inspections. According to PADEP Region 1 Office, the UST closures were approved by PADER on June 22, 1992. A description of the USTs removed, including the UST locations and the results of post-excavation soil sampling and analysis, are summarized below.

- Four 1,000-gallon gasoline USTs were removed from the Buckius Street Garage Area (Building 12 on Figure 3, likely in the vicinity of the RI soil boring location PCSB-01). TPH levels reported from the eight post-excavation soil samples ranged from non-detect to 190 mg/kg. A total xylene concentration of 0.019 mg/kg was reported in one of the eight samples. No BTEX were reported in any of the other samples. The excavation was backfilled with clean fill.
- One 1,000-gallon gasoline UST was removed from the Machine Shop Area (Building 12 on Figure 3). TPH levels reported from the three final post-excavation soil samples ranged from non-detect to 180

mg/kg. BTEX concentrations reported in the bottom sample ranged from 0.007 mg/kg (toluene) to 0.037 mg/kg (benzene). BTEX concentrations reported in the wall samples ranged from 0.007 mg/kg (toluene) to 0.18 mg/kg (benzene). Groundwater samples were also collected from seeps entering the excavation at three locations. Benzene was the only BTEX compound detected in the groundwater samples. Benzene was detected at 7 and 8 µg/L. A TPH concentration of 200 µg/L was reported in one sample. The excavation was backfilled with clean fill.

- Two 3,500-gallon diesel USTs were removed from the former scale house area (the scale house could not be located on historical figures). Post-excavation soil sampling indicated that TPH concentrations ranged from not detected to 220 mg/kg. No groundwater was observed in the excavation. The excavation was backfilled with clean fill.

2.4 EPA Environmental Indicator Determinations

In April 2013, EPA completed two Environmental Indicator Determinations concluding that both human exposures and impacted groundwater migration are under control at the Site. The Environmental Indicator process was initiated in response to a notification to PCC Land Company, Inc. (PCC) from EPA Region III on April 18, 2011. The notification included an attached letter dated June 22, 2010 prepared by PADEP requesting information regarding the status of the Site in relation to RCRA Corrective Action. In response to the notification, PCC conducted an August 11, 2011 site walk with PADEP and EPA's representative from Michael Baker International (Baker).

Based on the initial Site walk and file review, Baker prepared a January 2012 Environmental Indicator Inspection Report for the Site. Following the report, EPA issued the following RCRA Environmental Indicator Forms on April 10, 2013:

- CA-725: Current Human Exposures Under Control
- CA-750: Migration of Contaminated GW Under Control

The RCRA Environmental Indicator Forms concluded that both human exposures and impacted groundwater migration are under control at the Site. The RCRA Environmental Indicator Forms are provided as Appendix C. Any further work needed will be performed to satisfy the requirements of PADEP Act 2.

3 REMEDIAL INVESTIGATION

The RI was performed in two major phases. An initial phase of RI activities was performed by Paulus, Sokolowski and Sartor, Engineering, PC (PS&S) from 2003 through 2006 (hereinafter referred to as the Initial RI activities). Additional investigation activities were implemented by Arcadis in 2018 and 2019 (hereinafter referred to as the Supplemental Remedial Investigation [SRI] Activities). Each phase of the RI involved two or more rounds of fieldwork, with the scope of each round developed based on the results of preceding round(s). Between the Initial RI and SRI, the Site was unoccupied, and no activities were performed onsite other than periodic mowing of vegetation or maintenance of the perimeter fence.

The Initial RI activities consisted of sample collection from various media, including surface soil, subsurface soil, groundwater, soil gas, and ambient air to evaluate the nature and extent of impacts at the Site. Initial sampling locations were selected based on a review of available environmental database reports, Sanborn maps, aerial photographs, the RCRA Closure Report (including the associated soil and groundwater data), and other historical documents and figures. Test pit excavations and resulting soil samples were obtained from all areas of the Site, with the sampling locations generally biased towards the former operation areas. Subsequent phases of the Initial RI activities were developed to: (1) further delineate identified COCs; (2) complete characterization of the former operational areas; and (3) establish general Site conditions.

The SRI activities consisted of installing and sampling additional monitoring wells, soil borings, and test pits to: (1) confirm prior results, and that Site conditions had not significantly changed since samples were collected as part of the Initial RI activities; (2) fill identified data gaps from previous investigation and remedial activities and delineate the extent of impacts for purposes of developing a Cleanup Plan; and (3) assess current groundwater conditions.

The RI activities are summarized in Section 3.1 below and the RI findings are presented in Section 3.2.

3.1 Remedial Investigation Activities

The Initial and Supplemental RI activities consisted of the following:

- Excavating 197 test pits to characterize surface and shallow subsurface soil, evaluate subsurface structures, and assess geotechnical conditions. Soil samples from 145 test pits were collected for laboratory analysis.
- Installing 179[4] soil borings to characterize subsurface soils and Site stratigraphy. Soil samples from 150 soil borings were collected for laboratory analysis.
- Installing, developing, and sampling 33 shallow groundwater monitoring wells and 13 deep groundwater monitoring wells to characterize groundwater quality and evaluate groundwater flow.
- Drilling 7 hydropunch borings for a preliminary evaluation of groundwater conditions where visual impacts were observed.

[4] Count includes borings drilled for the monitoring wells installed in 2018 and 2019 because soil was characterized during drilling for the well installations.

- Collecting and analyzing approximately 540 soil samples and 112 groundwater samples for a combination of Target Compound List (TCL) VOCs, TCL SVOCs, Priority Pollutant (PP) metals, Target Analyte List (TAL) inorganics, cyanide, pesticides, and polychlorinated biphenyls (PCBs) to evaluate the nature and extent of environmental impacts in Site media.
- Collecting 21 soil gas samples and one ambient air sample to evaluate the potential for soil VI in future building development.
- Performing sediment probing in the Delaware River and a visual reconnaissance of the shoreline to evaluate nearshore conditions adjacent to the Site.
- Collecting data to support an ecological screening (ES; Section 6).

The test pit, soil boring, monitoring well, hydropunch boring, and soil gas sampling locations are shown on Figure 5. A summary of the laboratory analyses performed on soil samples collected from each soil boring and test pit is presented in Table 1, and a summary of the laboratory analyses performed on groundwater samples collected from each monitoring well and hydropunch location is presented in Table 2.

Sample collection was performed in accordance with PADEP guidelines and Act 2 requirements. The work conducted on the Site was performed in accordance with a site-specific Health and Safety Plan (HASP). The sampling activities, including techniques and analytical testing used to conduct this RI are presented below.

3.1.1 Initial Remedial Investigation Activities (2003-2006)

The Initial RI activities were performed through an iterative process from 2003 through 2006. These activities included the installation of test pits, soil borings, groundwater probes, and monitoring wells and the collection of soil, soil gas, and groundwater samples for laboratory analysis. To obtain data to characterize Site conditions a preliminary test pit and soil sampling program was conducted in March 2003 and additional field investigation activities were conducted from February through March 2005, and July 2005 through March 2006.

During the Initial RI activities, Earth Engineering Incorporated (EEI) also drilled soil borings and excavated test pits to collect soil samples for geotechnical testing. Based upon field observations and/or field instrumentation, select soil samples were also collected during the geotechnical investigation for laboratory analysis for Site-related COCs to aid in the Site characterization.

The components of the Initial RI activities are summarized in the table below.

Table 3-1: Overview of Initial RI Activities

Dates	Consultant	Sample Numbers	RI Activity
March 2003	PS&S	PSSTP-1 to PSSTP-30	Preliminary test pit investigation.
February 2005	EEI and PS&S	PC-B1 to PC-B15	Soil borings for geotechnical testing. Soil samples were collected for laboratory analysis at select locations, based on visible impacts.
February 2005	PS&S	PCTP-01 to PCTP-60	Second test pit investigation.
March 2005	EEI and PS&S	TP-01 to TP-78	Test pits for geotechnical testing. Soil samples were collected for laboratory analysis at select locations, based on visible impacts.
March 2005	PS&S	PCHP-01 to PCHP-07	Hydropunch sampling.
February and March 2005	PS&S	PCSB-01 to PCSB-25	Soil boring investigation.
July and August 2005	PS&S	PCSB-26 to PCSB-60	Additional soil boring investigation.
September 2005	PS&S	PCTP-61 to PCTP-79	Third test pit investigation.
August to October 2005	PS&S	PCMW-01 to PCMW-20S/D	Monitoring well installation.
November 2005 and January/ February 2006	PS&S	PCMW-01 to PCMW-20S/D	Groundwater investigations.
January 2006	PS&S	PCSV-01 to PCSV-22	Soil gas investigation.

The groundwater and soil samples were analyzed by Hampton-Clarke, Veritech Laboratories (Veritech), a PADEP certified laboratory (laboratory certification number #68-463), in accordance with EPA SW-846 methods. Approximately 350 soil samples were collected for laboratory analysis for TCL VOCs, TCL SVOCs, PP Metals, and total cyanide. Approximately 140 of these samples were also analyzed for PCBs and pesticides. A total of 7 groundwater samples from hydropunch borings and 66 groundwater samples from monitoring wells (obtained during two rounds of sampling the 33 monitoring wells) were collected and analyzed for TCL VOCs, TCL SVOCs, PP Metals (total and dissolved), PCBs and pesticides (monitoring well samples only).

Soil gas samples were analyzed by Air Toxics LTD, located in Folsom, California. The laboratory performed analyses via Modified EPA Compendium Method TO-15, plus Naphthalene, using GC/MS in

the full scan mode, as well as a Modified American Society Testing and Materials (ASTM) Method D-1946 for methane and fixed gases in air using gas chromatography with flame ionization detector (GC/FID) or gas chromatography with thermal conductivity detector (GC/TCD). Soil gas samples were analyzed in accordance with current methodologies that are consistent with the PADEP Technical Guidance Manual for Vapor Intrusion into Buildings from Groundwater and Soil Under Act 2 (PADEP 2021; TGM).

Details of the Initial RI fieldwork are provided in the subsections below.

3.1.1.1 Initial Soil Investigation

During the Initial RI activities conducted from 2003 to 2006, surface soil sampling (0 to 2 feet bgs) and a combination of test pits and soil borings to facilitate subsurface soil sampling (>2 feet bgs) were used to evaluate soil conditions. The test pit and soil boring locations are shown on Figure 5. The test pit and soil boring locations where soil samples were collected for laboratory analysis are shown on Figure 6.

Test Pits

The purpose of this test pit program was to:

- Characterize the horizontal and vertical extent of fill across the Site.
- Identify COCs in the various fill areas.
- Identify subsurface utilities that may have been abandoned in-place in former areas of operation.

PS&S conducted a preliminary test pit evaluation in March 2003 during which 30 test pits were excavated in the Former Coke Operations Area and the Fuel Blending Area. The geotechnical investigation involved advancing an additional 78 test pits. Based upon the findings of the initial round, subsequent investigations consisting of characterization and delineation of COCs were implemented. An additional 60 test pits were excavated from February 2005 through March 2005. From August through September 2005, 19 additional test pits were excavated to provide additional Site perimeter characterization data.

Long-reach backhoes were used to excavate test pits to define the depth of the fill areas prior to initiating the boring program. Test pits were located based upon review of Site historical maps, aerial photographs, and previous investigations.

Generally, soil samples were collected from the ground surface (0 to 6 inches) and at the fill and native soil interface (determined based upon visual and physical description). The test pit soil samples were collected using a dedicated polyethylene scoop and placed into laboratory-supplied sample containers. Two soil samples were typically collected from each test pit, although additional samples were collected at some locations based on visual observations.

Soil samples collected from the test pits were handled as follows: (1) screened for volatile organic vapors using a photoionization detector (PID); (2) observed for the presence of staining, discoloration, non-aqueous phase liquid (NAPL), ash, and tar; and (3) logged by a geologist using the Unified Soil Classification System (USCS). The information gathered during the test pit program was documented on test pit logs provided in Appendix D and summarized in Table 3.

Following completion of the test pits and the collection of soil samples, the test pits were backfilled with the excavated material and restored to the original grade. Upon backfilling of the test pits, material that

was not retained for laboratory analysis or placed back in the excavation was transferred to a roll-off container and disposed of in accordance with applicable federal, state and local regulations.

Soil Borings

The objectives of the soil boring program were to:

- Supplement the test pit program to further characterize the horizontal and vertical extent of fill material and to investigate the nature and extent of potential impacts to the native soils.
- Characterize the subsurface soils within the Former Coke Operations Area and Fuel Blending Area.
- Characterize Site stratigraphy.
- Identify physical characteristics of the subsurface soils.
- Identify potential physical and Site-related impacts in the Site soils resulting from the former Site operations.

Between February 2005 and October 2005, PS&S advanced a total of 60 soil borings. PCSB-01 to PCSB-25 were advanced in February and March 2005 using a conventional hollow-stem auger (HSA) drill rig and PCSB-26 to PCSB-60 were advanced in July and August 2005 using a GeoProbe direct push rig. Most borings were located within the RCRA Closure Areas, the Former Coke Operation Area, and the Fuel Blending Area. In February and March 2005, the soil borings were advanced through a silt and clay layer and into an underlying sand and gravel layer (between approximately 18 and 50 feet bgs). Three soil borings (PCSB-05, PCSB-13, and PCSB-16) were advanced through the sand and gravel layer and into bedrock. Based on observations from these soil borings, it was concluded that a silt and clay layer was continuous across the Site and acting as a confining unit for subsurface soil impacts. Therefore, soil borings drilled after March 2005 were only advanced into the silt and clay layer (i.e., confining unit). The geotechnical investigation consisted of the advancement of an additional 14 soil borings.

Subsurface soil samples were collected using a decontaminated split-spoon sampler advanced by the conventional HSA drill rig or macro-core liner advanced by the direct-push drill rig. In those instances where the HSA was used to penetrate the sand and gravel layer into the underlying confining unit, steel casing was used to prevent vertical migration of contaminants from the material within the fill layer.

Soil boring locations were selected to supplement the coverage provided by the test pits. The recovered soil samples were handled as follows: (1) screened for volatile organic vapors using a PID; (2) observed for the presence of staining, discoloration, NAPL, ash, and tar; (3) checked for odors; and (4) logged by a geologist using the USCS. The information gathered during the soil boring program was documented on soil boring logs which are contained in Appendix D and summarized in Table 3.

Generally, soil samples were collected from two or more depth intervals from each boring. The depth of the soil samples was based primarily upon field observations (i.e., visual observations, field screening results, etc.) that indicated potential impacts. In general, soil samples were collected at one or more of the above conditions:

- Surficial soils (the upper 0- to 2-foot interval).
- At the bottom of the encountered fill material or at the upper 2-foot interval of the native soils.
- A 6-inch interval (0- to 6-inches) immediately above the water table.

- Immediately above and below the silt and clay confining unit.
- At visually impacted zones and/or elevated PID readings.
- At the completion depth of the boring.

Following completion of the boreholes and the collection of soil samples, the boreholes were grouted to the surface using a cement-bentonite grout. All borings were finished to match pre-disturbance grades. Recovered soil sample material that was not retained for laboratory analysis was placed in a roll-off container and disposed of in accordance with applicable federal, state and local regulations.

3.1.1.2 Initial Groundwater Investigation

During the Initial RI activities, PS&S installed and sampled 20 shallow groundwater monitoring wells and 13 deep groundwater monitoring wells to characterize groundwater quality and evaluate groundwater flow. In addition, seven hydropunch borings were advanced and sampled to evaluate groundwater conditions. The hydropunch borings and monitoring well locations are shown on Figure 7.

Hydropunch Sampling

Following completion of the February and March 2005 test pit and soil boring program, initial groundwater sampling was conducted on March 24 and 25, 2005. A groundwater probe, or hydropunch, was advanced at seven locations in areas where visual impacts were observed during the initial soil investigation. The goal of the hydropunch sampling was to gather groundwater data to identify and generally characterize the constituents present in the shallow groundwater located in the fill above the confining silt and clay layer.

The groundwater samples were collected by driving hydropunch rods to the bottom of the designated sample depth interval and retracting 4 feet of the outer steel casing to expose a decontaminated stainless-steel screen. Actual sample intervals were determined based on observed field conditions (i.e., soil visual observations, soil field screening results, etc.).

The water collected in the sampling rod was poured directly into the laboratory-provided sample containers. The hydropunch rods were decontaminated between each sampling location. Any evidence of odors, sheens, or the presence of NAPL was noted. The observations and results were logged in project field forms. Upon completion of the sampling, each probe hole was left to naturally collapse into itself. All probe holes were restored at grade with the same material that was originally in place.

Monitoring Well Installation

Following completion of the test pit and soil boring phase of the Initial RI activities, a total of 33 monitoring wells were installed from August through October 2005 in accordance with the applicable PADEP Groundwater Monitoring Guidance Manual at the time. The monitoring wells were installed upgradient and downgradient of impacts identified during the soil boring and test pit program and at the property boundaries to serve as “point of compliance” locations. The geology at the monitoring wells was not documented (i.e., continuous soil samples providing soil classification by USCS were not collected from the soil borings drilled at the monitoring well locations; geology informing well construction was interpolated from observations at nearby borings and soil cuttings observed during drilling at the well locations). The wells were constructed as either shallow or deep wells based upon their screened depth in relation to the confining unit. The screen interval for shallow groundwater monitoring wells was installed

within the fill material above the confining unit, and the screen interval for deep groundwater monitoring wells was installed within the sand and gravel layer below the confining unit.

Of the 33 wells, seven were installed on the riverward portion of the Site and consisted of only shallow wells. The remaining 26 wells were comprised of 13 well clusters, each consisting of a shallow well and a deep well. Shallow wells are generally screened from 1 to 10 feet bgs near the river and from 5 to 15 feet bgs for the remainder of the Site. The deep wells are generally screened below the bottom of the silt and clay layer with a 10-foot screen between 18 and 40 feet bgs, depending on the depth of the silt and clay layer.

The shallow monitoring well construction consisted of 2-inch and 4-inch diameter casings. The 4-inch diameter wells were installed in the riverward portion of the Site. The deep monitoring wells were constructed as double cased wells. Six-inch steel casings were placed approximately 10 feet into the confining clay layer, through the overlying fill material, and grouted in-place. Following a minimum of 24 hours set time, the remaining depth of the boreholes for deep wells was drilled, and the wells were constructed from 2-inch diameter casings. The deep and shallow monitoring well were constructed with polyvinyl chloride (PVC) 20-slot well screens and PVC Schedule 40 casing. Typically, the monitoring well screen length was 10 feet and the casing extended from the top of the screen to grade.

A No. 2-grade sand pack was installed in the annular space from the bottom of the monitoring well screen to approximately one to three feet above the top of the well screen, except for shallow wells where the top of the screen was within one foot of the ground surface. In these shallow wells, the sand pack extends up to the concrete surface seal. A bentonite seal was placed into the annulus above the gravel pack. A bentonite/grout slurry was pumped into the annulus via a tremie pipe, from the top of the bentonite seal to the surface. The monitoring wells were protected and secured with above-grade (“stick-up”) locking steel casings. Well construction details are summarized in Table 4. Monitoring well construction logs are provided in Appendix D.

Following installation, the groundwater monitoring wells were developed by purging with a submersible pump. The development process continued until the turbidity readings were at or below 50 Nephelometric Turbidity Units (NTUs) or a two-hour development period, whichever occurred first. Development water was temporarily containerized onsite in 55-gallon steel drums. After waste characterization, containerized liquids were removed from the Site for proper offsite transportation and disposal.

Soil cuttings generated during the installation of each well were placed into a roll-off container and properly disposed of in accordance with applicable federal, state and local regulations.

Groundwater Sampling

The first round of groundwater sampling from the permanent monitoring wells was conducted approximately two weeks after well development in November 2005. A second round of groundwater sampling was completed in January/February 2006.

The monitoring wells were sampled using a “low-flow” sampling protocol. As part of the protocol, wells were purged at a low pumping rate using a Grundfos Rediflo® submersible pump or peristaltic pump and dedicated tubing. Prior to sample collection, groundwater was circulated through a flow-through cell to record pH, specific conductance, temperature, turbidity, dissolved oxygen, and oxidation-reduction potential. Following stabilization of the field parameters, groundwater was collected in laboratory-supplied sample containers. In those instances where a peristaltic pump was used to purge the well, the VOC

fraction of the sample was obtained using a dedicated bailer. The water level meters, submersible pump, peristaltic pump and flow cell were decontaminated prior to each use. Completed low-flow groundwater monitoring and purge logs are provided as Appendix E.

Water Level Measurements

During the above-identified groundwater sampling events, a complete round of groundwater level measurements was collected from the monitoring wells before sampling. Additional rounds of groundwater level measurements were collected in December 2005 and March 2006. The groundwater level measurement process documented the presence/absence of NAPL and the groundwater depth in each monitoring well. Groundwater depths were measured using a Solinst water level indicator to an accuracy of 0.01 feet. A Solinst oil/water interface probe, cotton string, and disposable bailers were used to determine if any NAPL was present in the monitoring wells. No measurable NAPL was identified during the two rounds of groundwater sampling other than an apparent emulsion at PCMW-05. Groundwater level data is discussed in Section 3.2.2. Water level measurements are presented in Table 5.

Hydraulic Conductivity Testing and Other Soil Physical Parameters

During the RI field program monitoring well installation activities, select soil samples were collected from the three Site strata to obtain the physical characteristics of this material through laboratory testing. Samples were collected in glass containers and Shelby tubes of the fill material, silt and clay layer, and sand and gravel layers. The samples were analyzed in the PS&S geotechnical laboratory for grain size, bulk density, permeability, and porosity. The data for these parameters were used to calculate hydraulic conductivity for each stratum. A copy of the soil physical parameter data is included as Appendix F.

3.1.1.3 Soil Gas Investigation

A total of 21 soil gas samples and one ambient air sample were collected at onsite locations in January 2006. The sampling locations were biased toward areas where visual observations and/or concentrations of VOCs and SVOCs were identified in Site soils and groundwater during the Initial RI activities. The sampling locations were concentrated toward the center, northeast corner, and eastern portions of the Site (see Figure 5 for the sampling locations). Soil gas samples were collected in unsaturated soil (i.e., fill) above the water table. The soil gas sampling locations were biased toward areas where visual impacts and/or elevated VOC or SVOC concentrations were identified in soil and groundwater. However, these locations may not have been ideal for soil gas sample collection because the water table was less than 5 feet bgs and the ground surface was not covered with an impermeable material (e.g., the ground surface at these locations consisted of soil or deteriorated asphalt).

The soil gas samples were obtained using a stainless-steel sampling system that uses driving rods (shaft sections) equipped with a small diameter hollow-tip sampling point (shield point). Teflon tubing was installed to allow extraction of soil gas samples. The shaft sections were driven into the ground to a depth of approximately one foot above the observed groundwater table. Due to the shallow groundwater at the Site, soil gas samples were generally collected at depths less than 5 feet bgs. The probe was then removed, leaving the expendable shield point and tubing in place allowing the collection of the soil gas sample.

The probe hole was sealed with bentonite to prevent intrusion of ambient “surface” air. Prior to the collection of soil gas, a vacuum pump was used to purge the line of ambient air at a rate of 0.1 to 0.2

liters/minute. Continuous or excessive pumping was avoided so that the soil gas would not be diluted with surface air.

Samples were extracted using Summa canisters attached to Teflon sample lines that extend from the shield points. Summa canisters were supplied by Air Toxics Limited (Air Toxics LTD) and evacuated to a vacuum pressure of approximately 30 inches of mercury. The pressure gradient between the vacuum in the canister and the subsurface atmosphere provided the driving force for sample flow and gas collection. The canisters were equipped with flow controllers with an integral vacuum gauge adjusted to provide a nominal one-hour integrated sample collection period (approximately 0.1 liters/minute). A vacuum gauge was used to measure the initial and final vacuum in the canister to document sample integrity. Following sample collection, real-time instrument readings were recorded for the presence of hydrogen sulfide, oxygen, carbon dioxide, and methane.

Soil gas sample integrity was maintained by using experienced field personnel, good sampling techniques, proper sampling equipment, and adequate documentation. Pre- and post-sample vacuum checks conducted in the field and at the laboratory demonstrated that leakage had not occurred before or after sample collection and provided documentation of sample integrity.

A field “replicate” soil gas sample was taken at two locations (one replicate for every 11 samples) to provide an assessment of the compositional consistency of the soil gas samples. One ambient air sample was also taken at a central location (adjacent to PCSV-22) for quality assurance and quality control (QA/QC) purposes.

After sampling was completed, the sample canisters were shipped overnight to Air Toxics LTD, located in Folsom, California for analysis. The laboratory performed analyses via the Modified EPA Compendium Method TO-15, plus Naphthalene, using GC/MS in the full scan mode, as well as a Modified ASTM Method D-1946 for Methane and fixed gases in air using GC/FID or GC/TCD. Analysis of a laboratory blank was performed by the laboratory as an internal QA/QC check.

3.1.2 Supplemental Remedial Investigation Activities (2018-2019)

The SRI Activities were performed in multiple phases from 2018 through 2019 to confirm the results and fill data gaps from the Initial RI work. Activities included additional groundwater and soil investigations, a Delaware River reconnaissance, and sediment probing in the nearshore area adjacent to the Site at low tide. As part of an interim Site review and inspection (performed between the Initial RI and SRI), GEI Consultants Inc. (GEI) performed Site walks on June 21, 2011 and July 12, 2011 to review current Site conditions. For purposes of this report, GEI’s activities and those activities performed by Herpetological Associates, Inc. as part of a July 2021 Phase 1 Aquatic and Nesting Habitat Survey for the new site owner, BP Bridesburg LLC (BPB) are presented together with the SRI Activities in Subsection 3.1.2.4. Most of the supplemental groundwater investigation was performed in 2018, and the supplemental soil investigation and sediment probing were performed in 2019. The components of the SRI Activities are summarized in the table below.

Table 3-2: Overview of SRI Activities

Dates	Sample Numbers	RI Activity
March 2018	MW-5, MW-6, and the 21 available PCMW- wells	Phase 1 groundwater investigation.
May 2018	MW-101 to MW-107, and seven PCMW- wells	Phase 2 groundwater investigation.
August 2018	PCMW-10D, PCMW-15S	Groundwater sampling for free cyanide.
March 2019	MW-107, PCMW-05, PCMW-16D	Groundwater sampling for total metals, dissolved metals, and TDS.
April and May 2019	S-101 through S-162, revisited 28 Initial RI Soil Sampling Locations (suffix “R” added to designate a revisited sampling location)	Phase 1 soil investigation.
April 2019	Not applicable	Delaware River reconnaissance and sediment probing.
September 2019	S-163 to S-173, MW-108 to MW-113, and PCTP-07R	Phase 2 soil investigation. Additional groundwater monitoring well installation.
October 2019	MW-108 to MW-113	Phase 3 groundwater investigation (groundwater sampling).

The groundwater and soil samples were analyzed by SGS North America Incorporated Laboratories of Dayton, New Jersey (SGS), a PADEP certified laboratory in accordance with the EPA SW-846 methods. A total of 186 soil samples were collected and analyzed for a combination of TCL VOCs, TCL SVOCs, TAL inorganics, total cyanide, pesticides, and PCBs. A total of 48 groundwater samples were collected and analyzed for a combination of TCL VOCs, TCL SVOCs, TAL inorganics (total and dissolved), total cyanide, pesticides, and PCBs. The laboratory analytical reports are provided in Electronic Attachment 4.

In addition, three groundwater samples were analyzed for free cyanide by TestAmerica, located in Amherst New York. The laboratory performed analyses via EPA SW-846 Method 9016.

3.1.2.1 Supplemental Groundwater Investigation

The supplemental groundwater investigation was performed to:

- Evaluate potential changes to groundwater conditions, if any, since the Initial RI activities and provide additional data to fully characterize the onsite extent of any impacts in Site groundwater (both shallow and deep groundwater zones).
- Help further refine the focus of the soil investigation (e.g., soil sampling targeted where groundwater impacts were observed).
- Fill data gaps that have been identified based on comparison of the Initial RI Activity data to the updated PADEP MSCs.

During the SRI, not all groundwater monitoring wells previously installed as part of the Initial RI or earlier investigations could be found or repaired for use in groundwater sampling. However, the existing wells that were found and the additional wells installed as part of the SRI provide sufficient coverage for evaluating groundwater flow patterns and water quality across the Site.

The first phase (Phase 1) of the SRI groundwater investigation fieldwork was performed between February 26, 2018 and March 23, 2018, and included land surveying, monitoring well integrity surveys, monitoring well redevelopment, water-level gauging, groundwater sampling and analysis, and a storm sewer reconnaissance.

The second phase (Phase 2) was conducted between May 8 and 31, 2018 to fill data gaps from Phase 1, including: (1) where certain previously-installed monitoring wells could not be located and sampled (the wells are considered lost or destroyed); and (2) where there were no previously-installed wells to evaluate conditions (e.g., downgradient from a former soil removal area and in certain areas where Initial RI soil investigation data suggested that residuals may remain).

The third phase (Phase 3) of the SRI groundwater investigation was performed on October 3 and 4, 2019 to evaluate groundwater conditions at: (1) locations where the SRI soil investigation identified a combination of visual impacts (e.g., coal tar-like material) and COCs at concentrations an order of magnitude or higher than potentially applicable PADEP MSCs; and (2) at the Site property boundaries and areas downgradient of Site-related impacts.

Monitoring Well Integrity Surveys and Redevelopment

Arcadis conducted well integrity surveys on February 26 and 27, 2018 to assess the condition of the existing groundwater monitoring wells at the Site (as those wells were installed more than 12 years earlier). Arcadis located 23 of the 33 stickup monitoring wells (wells identified by the prefix “PCMW-”), plus two of the nine monitoring wells that were of “unknown construction” (wells identified with the ID “MW-”). Based on the well integrity surveys, 23 of the 25 identified wells were found to be intact and usable for the groundwater investigation. Monitoring wells PCMW-7 and PCMW-12S were both found, but inspections with a downhole camera revealed that the well screens were damaged and blocked by roots and not usable for groundwater sampling. During Phase 2 investigation activities, the roots in monitoring wells PCMW-7 and PCMW-12S could not be cleared with available drilling equipment without irreparably damaging the wells. The monitoring well integrity survey forms are included in Appendix G.

The locations of the monitoring wells at the Site, with color-coding identifying those that were or were not found, are shown on Figure 7. As indicated by the figure, the usable existing wells in combination with the newly installed wells provided suitable coverage to evaluate the groundwater conditions across the Site.

Arcadis redeveloped existing monitoring wells on February 28, 2018 and March 5, 2018. This included monitoring wells where soft sediment was identified in the bottom of the well and where the measured depth of the well was less than the reported installation depth. Fine sands and silts were observed entering certain wells during redevelopment. The surging portion of the redevelopment process was discontinued at these wells to limit the potential for additional sediment accumulation in the wells.

Monitoring Well Installation

Arcadis installed monitoring wells MW-101 through MW-107 as part of the Phase 2 supplemental groundwater investigation and monitoring wells MW-108 through MW-113 as part of the Phase 3 supplemental groundwater investigation. These newly installed monitoring wells are in the shallow groundwater (water table) zone and screened within the fill material above the confining unit.

Phase 2 groundwater wells were installed from May 14 to 16, 2018 to provide coverage in the following areas of the Site:

- Where impacts were previously identified but the corresponding monitoring wells could not be located during the Phase 1 RI groundwater investigation.
- Downgradient from areas where Initial RI soil investigation data suggests that residuals may remain (e.g., soil containing NAPL and/or elevated concentrations of PAHs).
- Downgradient from a former soil removal area and near or along part of the property boundary where groundwater quality had not previously been evaluated.

Monitoring wells installed during the SRI to replace initial RI monitoring wells are identified in the table below.

Table 3-3: Replacement Wells

Initial RI Monitoring Well	Replacement Well	Notes on Location
PCMW-14S	MW-101	Slightly downgradient of PCMW-14S.
PCMW-13S	MW-103	Upgradient of PCMW-13S. Approximately hallway between PCMW-13S and PCMW-14S.
PCMW-16S	MW-105	In immediate vicinity of PCMW-16S.
PCMW-02	MW-106	In immediate vicinity of PCMW-02.

Phase 3 groundwater wells were installed on September 24 and 25, 2019 to provide coverage in and downgradient from areas where Site-related impacts were identified in soil and groundwater conditions were unknown.

The soil boring for MW-101 was advanced using conventional HSA drilling method, and soil samples from the boring were collected using a 2-foot-long, 2-inch-outside-diameter, split spoon sampling device. Based on the soil conditions observed at MW-101, Arcadis determined that using direct-push techniques would achieve good soil recovery and increase investigation efficiency. Therefore, soil borings for the remainder of the monitoring wells were advanced using the direct-push method and associated soil samples were continuously collected using a 5-foot macro-core liner. After the direct-push borings were completed, the borings were over-drilled using the HSA drilling method to enable installation of monitoring wells. This change was accomplished “on-the-fly” (without delay) using a drilling rig equipped with tooling for both methods. Monitoring well installation and boring logs are included in Appendix D.

The new groundwater monitoring wells were constructed using 2-inch-diameter Schedule 40 PVC pipe with a 0.010-inch slotted screen. The top of the screen was positioned approximately 1 foot above the water table, with the filter pack extending 1 foot above the top of the screen, a 1-foot thick bentonite seal above the filter pack, and at least 4 feet of solid PVC pipe extending below the ground surface. Screen lengths varied depending on the thickness of saturated shallow soil above the confining unit. The wells were protected at the surface using a 4-inch steel "stick-up" casing with a locking cap. The protective casings extend approximately 2.2 to 2.5 feet above ground surface and were set in concrete. Monitoring well construction details are presented in Table 4.

Soil Sampling

Soil samples recovered from the monitoring well borings were handled as follows: (1) screened for volatile organic vapors using a PID; (2) inspected for the presence of staining, odor, discoloration, NAPL, ash, and tar; and (3) characterized by a geologist (i.e., via soil classification by the USCS). The information gathered during the soil boring program was documented on soil boring logs which are contained in Appendix D and summarized in Table 3. Soil samples were collected from the borings during installation of MW-102, MW-103, MW-108, and MW-111 for laboratory analysis for the following reasons:

- MW-102 – A sample was collected to characterize a white plaster-like material that was encountered in the soil sample.
- MW-103 – Soil samples were collected at the water table and at the interface of the fill and silt and clay layer to evaluate soil conditions near sampling location PCTP-75 (adjacent to Buckius Street) where soil from 10-12 feet bgs was previously characterized (during Initial RI) as having an oil-like material and found to contain high concentrations of naphthalene.
- MW-108 and MW-111 – Soil samples were collected where the presence of coal tar-like material was observed and at the first interval without visual impacts or odors.

Soil samples were analyzed for TCL VOCs, TCL SVOCs, and TAL inorganics (including cyanide). The soil samples from MW-102 and MW-103 were also characterized for PCBs and pesticides.

Groundwater Sampling

Arcadis collected groundwater samples using low-flow methods on the following dates and at the following locations:

- *March 19 to 23, 2018* – groundwater samples were collected from the 23 monitoring wells that were found to be intact and usable during well surveying.
- *May 29 to 31, 2018* – groundwater samples were collected from monitoring wells MW-101 through MW-107, PCMW-04, PCMW-05, PCMW-06, PCMW-08S, PCMW-09S, PCMW-16D, and PCMW-19S.
- *July 27, 2018* – groundwater samples were collected from PCMW-10D and PCM-15S.
- *March 28, 2019* – groundwater samples were collected from MW-107, PCMW-05, and PCMW-16D.
- *October 4, 2019* – groundwater samples were collected from MW-108 through MW-113.

Field parameters (pH, conductivity, dissolved oxygen, temperature, turbidity, and oxidation-reduction potential) were monitored every five minutes during purging. After turbidity levels decreased to below the

50 NTU goal (where possible) and parameters stabilized, groundwater samples were collected for laboratory analysis. Groundwater sampling logs are included in Appendix E.

The groundwater samples collected in March 2018, May 2018, March 2019, and October 2019 were submitted to SGS Accutest of Dayton, New Jersey where they were analyzed as follows:

- Each groundwater sample was analyzed for TAL inorganic constituents, including total cyanide, except the May 30, 2018 groundwater sample collected from PCMW-16D.
- Each 2019 groundwater sample was analyzed for dissolved inorganics.
- March 2018, May 2018, and October 2019 groundwater samples were analyzed for TCL VOCs and TCL SVOCs.
- Each 2018 groundwater sample was analyzed for PCBs and pesticides.
- Select 2019 samples were analyzed for TDS.

The May 30, 2018 groundwater sample from PCMW-16D and the July 27, 2018 groundwater samples from PCMW-10D and PCMW-15S were submitted to Test America of Amherst, New York where they were analyzed for free cyanide. The free cyanide analysis was performed to evaluate the fraction of free cyanide present in the total cyanide concentration previously identified in samples from the respective wells. A sampling summary identifying each monitoring well and the corresponding sampling dates and laboratory analyses is presented in Table 2.

Water Level Measurements

Arcadis collected three synoptic rounds of groundwater level measurements on the following dates: (1) March 19, 2018 from 8:30 to 10:00 am, finishing approximately at low tide; (2) May 29, 2018 from approximately 9:00 to 11:00 am finishing approximately one hour after low tide; and (3) October 3, 2019 from 9:00 am to 1:00 pm finishing at low tide. Groundwater level measurements referenced to the North American Vertical Datum of 1988 (NAVD 88) are presented in Table 5. Groundwater potentiometric surface maps developed for the shallow and deep zones (for the above dates) are shown on Figures 8 through 12.

The groundwater flow patterns are consistent with those observed during the Initial RI activities. As indicated by Figures 8 through 10, shallow groundwater mounds in the central/southern portion of the Site and flows radially outward from the mound in all directions. As indicated by Figures 11 and 12, groundwater flow in the deep zone is eastward, toward the Delaware River.

3.1.2.2 Storm Sewer Reconnaissance

Existing site mapping shows a large City storm sewer identified as the “Upper Delaware Collecting Sewer” (reportedly 11-foot-3-inch to 12-foot-3-inch diameter) extending across the western portion of the Site, from the intersection of Bath Street with Orthodox Street to the south and Buckius Street to the north. The Upper Delaware Collecting Sewer conveys regional storm water deep beneath the Site. The sewer does not collect any storm water from the Site. The depth and construction of this sewer and the potential interaction (if any) between the sewer and shallow groundwater (whether groundwater may be infiltrating into the sewer, or the sewer may be leaking) were unknown prior to conducting the Phase 1 groundwater investigation.

Arcadis identified a manhole in the western portion of the Site (MH-4) within the approximate alignment of this sewer as shown on site mapping. The manhole location is approximately 175 feet south of the intersection of LeFevre Street and Garden Street, as shown on Figure 7. Arcadis observed a wire extending down in the manhole. Aboveground, the wire appeared to extend from MH-4 toward a nearby power pole with an elevated control box. The power pole is labelled, “Philadelphia Water Department, CSO Site, H07”. Downhole camera photos of MH-4 are shown below.

Figure 3-1: Downhole Photos of MH-4

Water was observed in the manhole at a depth of 26.5 bgs (equivalent to negative 13.29 feet NAVD 88). Groundwater elevations beneath the Site within the vicinity of the Upper Delaware Collecting Sewer range from approximately positive 6 to 8 feet NAVD 88, which is approximately 19 feet above the water level in the sewer. Based on this large head difference and as indicated in the existing shallow zone potentiometric surface maps, the Upper Delaware Collecting Sewer appears to have little or no influence on groundwater flow patterns at the Site. Accordingly, any groundwater collected by the sewer would be negligible.

3.1.2.3 Supplemental Soil Investigation

The supplemental soil investigation was performed to:

- Confirm that soil conditions have not changed since the Initial RI data were collected (i.e., that the existing data continue to be representative) and that Initial RI analytical data are still usable for developing the conceptual site model (CSM) and site cleanup plan.
- Delineate known impacted areas to assist in defining the limits of potential cleanup activities.

- Evaluate the elevation of the silt and clay confining unit to further assess the migration potential of any dense non-aqueous phase liquid (DNAPL) in the shallow groundwater zone.
- Investigate soil conditions along the property boundary to evaluate the potential for offsite migration of site-related constituents or DNAPL.

The first phase (Phase 1) of the soil investigation fieldwork was performed between March 25 and May 3, 2019, and included land surveying, subsurface utility clearance, soil borings, and test pit installation.

The second phase (Phase 2) was conducted between September 19 and 25, 2019 to fill data gaps from Phase 1, where: (1) soil exhibited a combination of visual impacts (e.g., coal tar-like material) and COCs at concentrations an order of magnitude or higher than potentially applicable PADEP MSCs; and (2) data for nearby locations were insufficient to evaluate extent of the impacted soil requiring removal/in-situ treatment.

Soil samples were collected from soil borings or test pits, depending on the purpose of each sampling location, and submitted for laboratory analysis. Soil borings were used more frequently to achieve sampling depths to the confining unit. Test pits were used in locations where subsurface structures were expected and where a broader evaluation of shallow subsurface soil was desired.

Soil Borings

Arcadis advanced a total of 80 soil borings during Phase 1 and a total of 12 soil borings during Phase 2. These numbers are in addition to the soil borings drilled to install monitoring wells MW-101 through MW-113. To confirm Initial RI soil analytical results, approximately 10% of the Initial RI soil sampling locations were revisited and sampled. In total, 25 soil borings revisited previous soil sampling areas, 21 of which were originally test pit sampling locations. Revisited sampling locations were selected to: (1) provide spatial coverage across the site; and (2) represent a range of conditions (e.g., highest concentrations, medium concentrations, and lowest concentrations, with approximately equal focus on each concentration range). Revisited sampling locations were also selected to provide site-wide information on the elevation of the confining silt and clay layer.

Soil borings were drilled into the silt and clay layer using direct-push methods. Soil samples were continuously collected from the borings using a 4-foot-long, 1.5-inch-inside-diameter macro-core sampling device. Recovered soil samples were visually characterized (for color, texture, and moisture content) and were screened using a PID. The presence of visible impacts (e.g., tar-like material, sheens) and obvious odors encountered in the soil were documented. The information gathered during the soil boring program was documented on soil boring logs which are contained in Appendix D and summarized in Table 3.

One or more soil samples were collected from 86 of the soil borings drilled for laboratory analysis. Selection of soil samples for laboratory analysis was primarily based on visual observations and data from nearby Initial RI sampling locations. The proposed sample depths were generally selected for laboratory analysis following one of the scenarios below:

- *Scenario 1* – For revisited sampling locations, samples were collected at approximately the same depth intervals as the Initial RI samples. As needed, additional samples were collected from these locations based on visual observations and at the discretion of the onsite geologist overseeing the work (e.g., if the geologist observed visual impacts, obvious odors, or elevated PID readings not previously documented at the sampling location).

- *Scenario 2* – For sampling locations where visible staining, tar-like material, obvious odors, or elevated PID readings were identified, one sample was collected from the "worst-case" sampling interval and a second sample was collected from the first apparent "clean" interval underlying the impacted materials.

- *Scenario 3* – For perimeter sampling locations where no visible staining, NAPL, obvious odors, or elevated PID readings were identified, one surface soil sample (0-0.5 feet bgs) and one shallow subsurface soil sample (0.5-2 feet bgs) were collected for laboratory analysis.

- *Scenario 4* – If the scenarios above did not apply, two samples were collected from depths selected based on nearby Initial RI sampling locations and identified data gaps.

Soil samples were not collected from below the water table (as identified by saturated soil in the soil boring) for the Phase 2 soil investigation.

Soil samples collected for laboratory analysis were generally analyzed for TCL VOCs, TCL SVOCs, and TAL inorganics including cyanide, except as indicated:

- Samples from S-101 through S-104 were only analyzed for TCL VOCs and SVOCs.
- Samples from S-138 through S-140 were only analyzed for PCBs.

Surface soil samples from PCSB-30R, PCSB-41R, and PCTP-73R and revisited sampling locations from the Initial RI's PSSTP- series were also analyzed for PCBs and pesticides. A summary of the laboratory analyses performed in soil from each soil boring is presented in Table 1.

Test Pits

Arcadis excavated nine test pits during Phase 1 of the supplemental soil investigation. No test pits were excavated during Phase 2. To confirm Initial RI soil analytical results, three of the test pits were excavated at revisited sampling locations, one of which was originally a soil boring location.

Test pits were excavated using a rubber-tire backhoe. Soil excavated from each 2-foot depth interval was visually characterized (for color, texture, and moisture content) and screened using a PID. The presence of visible impacts and obvious odors encountered in the soil was documented. The information gathered during the test pit excavations is documented on the logs included in Appendix D and summarized in Table 3.

One or more soil samples were collected from eight test pits for laboratory analysis. Selection of soil samples for laboratory analysis was primarily based on visual observations and data from nearby Initial RI sampling locations and in general, followed the same sampling scenarios as the soil borings.

Soil samples collected for laboratory analysis were generally analyzed for TCL VOCs, TCL SVOCs, and TAL inorganics including cyanide, except one of two soil samples from S-142 (i.e., from 6-6.5 feet bgs) was only analyzed for cyanide because of the potential presence of purifier waste. An underlying sample from S-142 (7-8 feet bgs) was analyzed for TCL VOCs, TCL SVOCs, and TAL inorganics including cyanide. Additionally, soil samples from PCSB-26R and PCTP-66R were analyzed for PCBs and pesticides. A summary of the laboratory analyses performed in soil from each soil boring is presented in Table 1.

3.1.2.4 Delaware River Reconnaissance and Sediment Probing

To evaluate potential impacts from the Site to the Delaware River, Arcadis performed reconnaissance activities along the shoreline adjacent to the Site. Initial evaluations of the shoreline were performed on March 25 and April 8, 2019. Additional evaluations of the shoreline were performed on May 3 and November 12, 2019. During these site visits, the shoreline was assessed for sheens, tar-like material, elevated PID readings, or other observable indications of Site-related impacts, and the current shoreline conditions were photo-documented during the low tide.

The shoreline was found to contain a rubble-armored seawall (i.e., riprap-like material), two dilapidated piers, and a narrow sandy/gravel area. Additionally, a shopping cart, three submerged vehicles, and other trash were observed along the shoreline. From reconnaissance conducted along the tidal shoreline habitat at low tide, no visible impacts (e.g., sheens) to sediment were observed.

Arcadis evaluated potential habitat for the northern red-bellied cooter during a November 12, 2019 site visit. The northern red-bellied cooter had been identified by the Pennsylvania Fish and Boat Commission (PFBC) as a threatened species in the area of the Site. Arcadis did not encounter prime habitat for the red-bellied cooter or any rare plant or wildlife communities. Observations indicated limited basking habitat areas along the near-shoreline tidal areas. Bohler Engineering performed an additional habitat survey on May 25, 2021, and findings from the survey were developed into a Phase 1 Aquatic and Nesting Habitat Evaluation (Exhibit 2).

Arcadis visually assessed and surveyed Outfall 001 south of the southernmost pier and a potential transfer pipe on north side of northern pier. GEI had also assessed Outfall 001 during its Site walks and found no impacts. Outfall 001 is constructed of concrete and approximately two feet in diameter. At low tide the pipe is fully exposed, except where it is silted in with surrounding sand, gravel, and debris. The potential transfer pipe is constructed from steel and approximately 8 to 12 inches in diameter. This pipe is level with the top of the pier and is not expected to be submerged at any point of the tidal schedule. No discharges were observed during Arcadis' or GEI's Site visits. A photograph of Outfall 001 at low tide is shown as Figure 3-2. No site-related environmental impacts were observed at Outfall 001.

Sediment probing was performed on the shoreline adjacent to the Site on May 3, 2019 during low tide. Probing was done from south of the northernmost pier to the southern property boundary and extended approximately 20 feet

Figure 3-2: Outfall 001

from the shore into the Site. Probing was performed approximately every 2 feet in this area to evaluate the presence of any sheens, seeps, or other indications of Site-related impacts. The sediment was soft and silty. A metal rod was commonly advanced 3 to 4 feet in the sediment and at some locations up to 5 feet into the sediment. No oil-like sheens, elevated PID readings, or noticeable odors were observed. Volatile organics were not detected (i.e., PID readings were 0.0 parts per million [ppm]) at these film locations. Based on the probing observations, sediment was not further evaluated.

3.1.3 Ecological Evaluation

Arcadis performed an ecological evaluation to support the development of the Ecological Screening (Section 6). The evaluation generally consisted of the following three parts:

- An onsite wetland delineation.
- A formal review of potential threatened and endangered species that may be on or in the vicinity of the Site from Pennsylvania Department of Natural Resources (PADNR) in conjunction with United States Fish and Wildlife Service (USFWS) in response to a request from Arcadis in the form or a Pennsylvania Natural Diversity Inventory (PNDI) receipt submitted on October 3, 2019.
- An onsite habitat delineation.

Findings of the ecological evaluation are provided in Section 6.1.

3.1.4 Decontamination

Sampling equipment was decontaminated before implementing sampling, probing, and drilling activities and between boring locations. Excavation and drilling equipment, including augers and split spoon samplers, were decontaminated using a steam cleaner or hot water pressure washer over a temporary decontamination pad or 55-gallon drum. Non-dedicated sampling equipment was decontaminated between each use by steam cleaning and/or thoroughly washing with alconox and water, using a brush to remove particulate matter or surface film, followed by a thorough rinsing with tap water. Liquids generated from the decontamination process were pumped into 55-gallon steel drums and disposed of in accordance with federal, state and local regulations.

3.1.5 Air Monitoring

During the Initial RI, a PID, quad gas meter and dust monitor (data RAM) were used to monitor volatile organic vapors, hazardous vapors and soil particulates, respectively, in the breathing zone during ground intrusive activities. During field activities that used the HSA drilling method or during test pit excavation activities, calibrated air monitoring instruments were also employed to monitor for potential releases of VOCs and dust at upwind and downwind air monitoring stations. The monitoring instruments were calibrated on at least a daily basis. Equipment calibration was documented in the project field forms and instrument calibration logs. The results of the perimeter air monitoring showed no exceedances of VOC levels or levels of particulate matter with a diameter less than 10 microns as a result of the ground intrusive activities.

Based on the observations during the Initial RI activities, monitoring during the SRI was conducted only in the worker breathing zone for volatile organic vapors using a PID. Perimeter air monitoring was not performed during the SRI. No elevated PID readings were observed in the work breathing zone.

3.1.6 Surveying

During the Initial RI activities, the locations, measuring point and surface elevations of test pits, new monitoring wells, soil probes/borings, and groundwater probes were either surveyed by a licensed surveyor or documented using a field global positioning system (GPS) unit and placed on a georeferenced base map. Top of casing and associated ground surface elevations were surveyed. These data were used in determining groundwater elevations.

Arcadis's survey subcontractor, Paul James Olszewski, PLS, PLLC (PJ Olszewski), established three semi-permanent survey control points at the Site relative horizontally to the North American Datum of 1983 State Plane of Pennsylvania-South (NAD 83) State Plane of Pennsylvania-South and vertically to NAVD 88. Each semi-permanent survey monument was tied into at least three planimetric features. Using the semi-permanent survey control points, PJ Olszewski resurveyed the located monitoring wells that remained from the Initial RI. The top of outer casing, top of inner casing, and ground surface elevations for each groundwater monitoring well were surveyed relative to NAVD 88. PJ Olszewski also surveyed the horizontal location and rim elevation of the Upper Delaware Collecting Sewer manhole MH-4 and subsurface piping and structures encountered at the Site. The horizontal location and ground surface elevation of each soil sampling location were also surveyed relative to NAD 83 and NAVD 88. The groundwater monitoring well, soil boring, test pit, MH-4, and subsurface pipe coordinates and elevations are presented in Table 6.

Before implementing the supplemental soil investigation, PJ Olszewski laser-scanned four preliminary soil delineation areas and associated building foundation areas. Laser technology measures distance with laser "time of flight" and then verifies the space with "wave technology" to generate a point cloud of data that is subsequently overlain by high-definition black and white photographs. The combination of the technologies and smart software tools allows for survey quality measurements of an entire area. The scanned areas were selected based on review of the Initial RI activities. Laser scanning technologies provided detailed survey ("point cloud" data) of the primary areas of interest at the Site in areas where the most significant impacts were suspected to be present. The survey and site photographs were used to evaluate/select SRI sampling locations based on surface condition, vegetation density, and proximity to remaining site features.

Arcadis used a handheld Trimble Geo 7X GPS to survey water and wetlands boundaries. A handheld Trimble R1 GPS was used to survey other points of ecological interest, Outfall 001, and the potential intake pipe.

3.1.7 Data Management and Quality Control

The data quality objective was to obtain valid data to be used to determine the nature, extent and sources of COCs at the Site. For the SRI, the QA/QC samples were collected in accordance with the most recent version of National Grid's generic Field Sampling Plan/Quality Assurance Project Plan. In addition, Arcadis performed a Tier 2 validation for each sample delivery group. Findings of the validation process are documented in the Data Usability Summary Reports included in Appendix H.

To document data quality in the soil and groundwater analyses, several types of QA/QC measures were implemented. QA/QC samples were collected (field blanks, matrix spikes and matrix spike duplicates) at a rate of 1 per 20 environmental samples (soil and groundwater). Trip blanks accompanied shipments of water samples that required volatile organic analysis. Samples for organic analyses were spiked with surrogate and/or internal standard compounds in order to determine the integrity/reliability of the sample results.

To determine the comparability of the sample results, matrix spikes and matrix spike duplicates were analyzed. In addition, specific laboratory QA/QC measures were taken during analysis (i.e., calibrations, blanks, control samples, spiked blanks, etc.), as required by the analytical methods.

3.1.8 Waste Management

All investigation-derived waste was contained onsite for waste characterization before offsite disposal. Soil cuttings, personal protective equipment (PPE), and spent disposable sampling materials were segregated by waste type and placed in United States Department of Transportation- (USDOT-) approved 55-gallon steel drums. Decontamination water, purged groundwater, and drilling water was stored in 55-gallon drums.

During the SRI Activities, a total of 13 drums of non-hazardous liquids (consisting of purge, decontamination, and well-development water), 5 drums of non-hazardous solids (consisting of drill cuttings, decontamination pad materials, and probe liners), and 4 drums of lead-hazardous soil mixture (EPA waste code D008) were generated. Drums were managed and removed from the Site under the direction of National Grid's Waste Management subcontractor, Capital Environmental. Waste characterization and disposal documentation is presented in Appendix I.

3.2 Remedial Investigation Findings

This section presents the findings of the RI activities described in Section 3.1. Visual impacts, PID headspace readings, and laboratory analytical results are used together to form a "weight of evidence" to evaluate Site-related impacts and cleanup requirements. A discussion of regional geology in the vicinity of the Site is presented below, followed by a discussion of the Site geology and hydrogeology, distribution of visual impacts, and sampling results for soil, groundwater, and soil vapor.

3.2.1 Physical Setting and Geology

The Site is situated on the westernmost margin of the Atlantic Coastal Plain Physiographic Province. The Coastal Plain is a narrow strip of land in southeastern Pennsylvania. The entire area is about 45 miles long and up to five miles wide and runs parallel to the Delaware River. Most of the Coastal Plain deposits are sand, gravel, silt and clay, which drape over crystalline igneous and metamorphic rocks. The Coastal Plain deposits range in thickness from a thin film at edge of the Coastal Plain to over 6,000 feet beneath the mouth of Delaware Bay (PADEP 2001).

The Site is within the Lower Delaware River Watershed (Hydrologic Unit Code 02040202), which encompasses approximately 1,151 square miles. The watershed is primarily characterized as urban, industrial, and agricultural lands. The region is characterized by sands and gravels storing large quantities of water with extensive streams and wetlands present. Precipitation is primarily adsorbed through direct

infiltration processes into surface soils or absorbed through root uptake by vegetation. As mentioned in Section 2.1, vegetation cover exists throughout a large portion of the Site, and limits potential for dust generation or migration to downgradient areas.

According to the Soil Survey of Bucks and Philadelphia Counties (USDA 1975), soil in the vicinity of the Site is characterized as Urban Land. Areas characterized as Urban Land are often so disturbed by construction that identification is not practical. Native soils are typically displaced by fill material during construction activities. Subsurface investigations confirm the presence of substantial fill materials above native soils at the Site. Fill materials consist of cinders, metal, glass, brick, concrete rubble, coal, ash, and cinders comingled with varying amounts of sand and gravel. The fill material at the Site generally meets the definition of historic fill described in Pennsylvania Department of Environmental Protection's Management of Fill Policy (Document #258-2182-773) dated January 1, 2020. The fill material at the Site ranges in thickness from approximately 10- to 20-feet and is thickest in the northeast portion of the Site. In general, the fill thickness decreases from north to southeast, where it pinches out near the Delaware River. The regional geography near the Site is shown on Figure 13.

An organic-rich silt and clay layer underlies the fill material beneath the entire Site. The silt and clay layer was the original land surface prior to filling and development of the area and was likely deposited in a flood-plain/marshy area of the Delaware River. The silt and clay ranges in thickness from approximately 5- to 45- feet and is thickest in the eastern portion of the Site, near the Delaware River. This confining unit was determined to be the separation between the shallow and deep groundwater at the Site and for practicable purposes prevents the movement of groundwater between the shallow and deep groundwater zones at the Site.

Fine-to-coarse sand and gravel of the Pennsauken Formation is observed beneath the silt and clay. Only two Site borings (PCSB-05 and PCSB-16) penetrated the sand and gravel unit, and the thickness of the sand and gravel at these locations was approximately 40 and 60 feet bgs, respectively. Weathered metamorphic schist (saprolite) of the Wissahickon Formation was observed at borings PCSB-05 and PCSB-16 at approximately 70 and 85 feet bgs, respectively. At boring PCSB-13, the sand and gravel unit was estimated to be 10 feet thick and schist was encountered at 36 feet bgs. A cross-section location map and two geologic cross-sections are provided on Figures 14 through 16.

3.2.2 Hydrogeology

Regional groundwater generally flows from the northwest to the southeast, toward the Delaware River. Groundwater elevation data at the Site was measured on October 31, 2005, December 30, 2005, January 30, 2006, March 14, 2006, March 19, 2018, May 29, 2018, and October 3, 2019. The March 14, 2006 data include groundwater elevation data collected during both high and low tides in the Delaware River to assess tidal influence on the shallow and deep groundwater at the Site. The monitoring conducted to date does not indicate a tidal influence on the Site other than at select deep monitoring well locations where levels change by generally less than 1 foot between low and high tides. The groundwater measurements are presented in Table 5. Groundwater contour maps for the shallow and deep groundwater are shown on Figures 8 through 12.

Three hydrostratigraphic units exist at the site: the fill, silt and clay, and sand and gravel. Hydrostratigraphic units are defined based on formations that have similar hydraulic properties. The water table is encountered in the urban/historic fill unit across the site at depths of approximately 2- to 12- feet

bgs. Based on regional groundwater information, this shallow groundwater zone is a perched aquifer that was created by the placement of fill over the native silt and clay layer. Composition of this groundwater zone is expected to be heavily influenced by the urban/historic fill, and therefore, the groundwater is not suitable for use. As shown on Figures 8, 9, and 10, groundwater in the fill is mounded in the central/southern portion of the Site and flows radially outward from the mound. The horizontal hydraulic gradient in the fill is approximately 0.005 to 0.01, depending on location. It appears that flow in the fill is largely controlled by the topography of the underlying silt and clay. That is, where the silt and clay unit has a higher topographic relief, the water table is also higher in elevation. A small amount of groundwater is expected to leak downward and into the silt and clay unit, as demonstrated by a downward hydraulic gradient that exists between the fill and sand and gravel of approximately 0.27. The hydraulic conductivity of the fill ranges from approximately $1.47x10^{-4}$ to $2.93x10^{-3}$ centimeters per second (cm/sec)[5].

Groundwater flow within the silt and clay is expected to be minimal due to its low permeability. The hydraulic conductivity of the silt and clay is calculated to be approximately $8.76x10^{-8}$ to $1.38x10^{-7}$ cm/sec. Flow within this unit is both horizontal and downward into the sand and gravel.

The potentiometric surface within the sand and gravel of the deep aquifer zone is observed at approximately 9- to 17-feet bgs. The deep aquifer is the primary groundwater aquifer for the Philadelphia region. Groundwater elevations in the sand and gravel do not appear to vary as much as those in the fill, likely because of hydraulic connection with the Delaware River. As indicated by Figures 11 and 12, groundwater in the sand and gravel flows eastward, toward the Delaware River. The horizontal hydraulic gradient in the sand and gravel is approximately 0.00043. The sand and gravel is the most permeable hydrostratigraphic unit beneath the site and has a hydraulic conductivity of $2.73x10^{-3}$ to $1.79x10^{-1}$ cm/sec.

3.2.2.1 Local Wells and Groundwater Use Around the Site

Per the Philadelphia Water Department Records, residents around the Site consume city water. However, according to the Pennsylvania Groundwater Information System (accessed via the internet on October 13, 2020), there are a total of 65 groundwater wells within a ½-radius around the Site boundaries. Groundwater wells within a ½-mile radius around the Site boundaries are shown on Figure 13 and local well details are presented in Appendix J. Per well type, the number of local wells around the Site are as follows:

- 55 Unused/Abandoned/Destroyed Wells
- 6 Groundwater Monitoring Wells
- 1 Unknown Withdrawal Well
- 1 “Domestic Withdrawal Well”
- 2 Other Withdrawal Wells

A total of 38 of the 65 wells around the Site are directly related to the environmental investigation and cleanup efforts at the former Rohm and Haas Chemical Company Facility (Pennsylvania Facility ID 742771 and NIR number 61614). This facility is approximately 1/3 mile north of the Site. Three monitoring

[5] Hydraulic conductivity values were calculated based on slug test data reported by WCC (WCC 1986) and laboratory soil testing results reported by PSS.

wells, the two “other withdrawal wells”, and the one “unknown withdrawal well” appear to be directly related to the former Rohm and Haas Chemical Company environmental investigation and cleanup.

The one “domestic well” located near the Site is also listed as a monitoring well. This well is located on 3099 Orthodox Street immediately south of the Site at a facility with an active environmental cleanup (Facility ID 609536). This well appears to be related to a former diesel spill from a UST (Pennsylvania Notification of Contamination Form number 33352). For this reason, it is likely that the well is only used for monitoring.

The cluster of wells on the south side of Orthodox Street (immediately south of the Site) appear to be related to an environmental cleanup effort for USF Holland Inc (Pennsylvania Facility IDs 608210/832196 and NIR number 69661).

In conclusion, groundwater around the Site is not used for potable purposes and groundwater wells installed around the Site are generally only used for environmental investigations and clean-ups.

3.2.3 Visual Observations / Headspace Readings

Soil samples collected from soil borings and test pits underwent visual inspection and field screening with a PID. The observed Site-related impacts were characterized by degree of impact. For purposes of characterizing visual observations in the soil, three categories are used to describe the observed impacts as follows (ordered from most impacted to least impacted):

- *Viscous tar or oil-like material* – Viscous or tacky substance that is in a liquid or partially liquid phase. Viscous tar or oil-like material was sometimes observed throughout the soil sample and in the pore space around soil granules. The magnitude of the observed tar was also described (e.g., coated, stringers or blebs).
- *Solidified tar or tar-like material* – Residual tar or similar material that is in a semi-solid to solid phase.
- *Sheen* – Soil and/or groundwater exhibiting an iridescent or rainbow petroleum-like sheen.

Based on the three categories above, 118 of the 377 test pits and soil borings exhibit visual impacts from former Site operations. Visible staining was observed in soil from an additional 15 sampling locations. Pockets of viscous tar or oil-like material were observed in 20 test pits and soil borings. Solidified tar or tar-like material was observed in 43 test pits and soil borings. Sheens were observed in soil from 77 test pits and soil borings. Odors were noticed at approximately 135 test pits and soil borings. Field observations are summarized in Table 3. Photographs of soil sampling intervals collected from the SRI are included as Electronic Attachment 5.

The Site-related visual impacts were predominately encountered within the central portion of the Site surrounding the Former Coke Operations Area and structures (i.e., former tar storage area, former by-products building and former oxide boxes). Isolated areas of visual soil impacts were encountered at locations on the remainder of the Site. The observed visual impacts in the central portion of the Site were generally associated with the former process piping and foundations, except for impacts found near the former AST farms, east of Former Byproducts Building (later in this RI Report referred to as Area 4). Table 3 summarizes the impacts encountered at the soil boring and test pit locations and identifies the general area of the site where each boring/test pit was completed. Additionally, the extent of Site-related

visual impacts and the designated color scheme representing the three categories above (e.g., viscous tar or oil-like material, solidified tar or tar-like material, and sheen) are shown on Figure 17.

Occurrences of viscous tar or oil-like material are limited to the central portion of the Site surrounding the Former Coke Operation Area, except at the following locations: PCSB-01, PCTP-66, PCTP-75, PSSTR-04R, and S-151. The quantity of viscous tar or oil-like material was not well documented during the Initial RI. For the SRI, viscous tar was generally only observed as stringers or blebs, except at sampling locations PCTP-17R, S-160, and S-161 where lenses of coal-tar like material were encountered in available pore space. Sampling locations with viscous tar or oil-like material have been revisited, and viscous tar or oil-like material in surrounding soil has been delineated. Viscous tar or oil-like material in the center of the Site have also been delineated.

Visual impacts are limited to the fill layer or the top two feet of the silt and clay layer, except at soil boring location PCTP-17R near the Former Tar Holders where visual impacts were observed 8 feet into the silt and clay layer. Based on observations at PCSB-09 (located approximately 30 feet northeast of PCTP-17R), the silt and clay layer is approximately 25 feet thick at PCTP-17R. Both PCSB-09 and PCTP-17R are shown on cross-section A-A' (Figure 15). If visual impacts were encountered in a soil boring, the soil boring was advanced to at least the first "clean" interval where no visual impacts or odors were observed. No impacts were observed penetrating the confining silt and clay layer. Within the fill layer, the depths of the visual impacts ranged from surface soils to the bottom of the layer (up to 22 feet bgs) depending on location. Odors were noted at depths up to 26 feet bgs.

For the revisited sampling locations, the visual observations from the SRI Activities are generally consistent with or indicate lesser degree of impacts than those originally documented during the Initial RI activities. In total, seven sampling locations where PS&S observed viscous tar or oil-like material were revisited, and Arcadis only confirmed the presence of this material at one location (PCTP-17). In addition, Arcadis encountered viscous tar or oil-like material at a revisited sampling location (PSSTP-04R) where PS&S did not observe this impact during the Initial RI Activity. The variation between locations where viscous tar and oil-like material were observed during the Initial RI and SRI indicate that viscous tar and oil-like material is not as extensive and/or contiguous as the Initial RI indicates. Therefore, locations with viscous tar and oil-like material are likely limited in size and were not reproduceable.

Generally consistent observations of solidified tar, staining, and sheens were observed between original and revisited sampling locations. For the revisited sampling locations, the reported top of clay surface depths (when encountered) were generally within 1 to 3 feet of that reported for the original boring, except for PCTP-10 and PCTP-32 where the clay surface depths are reported with an 8-foot and 10.5-foot difference, respectively (neither of these locations exhibit viscous tar or oil-like material). In addition, the reported groundwater depths at each soil sampling location were generally reported within 1 to 4 feet from Initial RI and SRI activities. The difference in observations from the Initial RI and SRI Activities is potentially due to a combination of factors, including the potential difference in sampling method (test pits vs. soil borings), survey discrepancies[6], changes in location because of access issues (e.g., because of vegetation or terrain), difference in precipitation and infiltration at the time of sampling, and interpretation

[6] A horizontal datum was not referenced during the Initial RI activities. When revisiting the sampling locations, Arcadis used the horizontal coordinates available in PS&S notes and from their existing Geographic Information System map.

of conditions by different onsite geologists. To help distinguish between the SRI and the Initial RI sample locations, the SRI sample locations are shaded in gray on Table 3, and the SRI data for a revisited sampling location is presented immediately after the Initial RI data.

PID headspace readings greater than zero ppm are also presented in Table 3. Figure 17 also indicates locations where PID headspace readings are greater than or equal to 100 ppm. Although there is no regulatory screening value for PID readings, the observations are used in conjunction with visual impacts to gather a "weight of evidence" of Site-related impacts to inform the Site cleanup and redevelopment plan. Additional information about the PID readings is provided below.

A total of 12 sampling locations with visual impacts also had volatile organic vapors at concentrations greater than 100 ppm. However, PID headspace readings greater than 100 ppm were also encountered at 13 sampling locations where no visual impacts were observed. The highest PID readings were encountered at PCSB-01R which is in the northeast-most corner of the Site. At this location, the PID identified volatile organic vapors greater than 15,000 ppm (instrument maximum) from 16 to 17 feet bgs. The elevated PID readings immediately dropped to 23.1 ppm at the next interval. The initial interval with an elevated PID reading at PCSB-01R was from 14 to 15 feet bgs at 111.8 ppm. Initial RI PID Readings from PCSB-01 peaked at 1,050 ppm from 14.5 to 15 feet bgs. The second highest PID reading was observed at SRI boring location S-144 (458.9 ppm from 14 to 15 feet bgs) which is a step-out delineation boring beyond PSCB-01R, and the third highest PID reading was observed at PCSB-45 (349.2 ppm) which is in the Fuel Blending Area where URS encountered fuel oil impacts in 2001.

3.2.3.1 Potential Purifier and Spent Iron Oxide Waste

During soil sampling activities, bluish-green colored material (possibly wood chips interspersed in soil) was observed at four locations and conservatively interpreted in the field to be potential purifier waste. Purifier wastes are typically composed of lime or an iron-impregnated cellulose-based matrix (like sawdust or wood chips) and often contain cyanide (commonly as insoluble, complexed ferrocyanide salts). Cyanide complexes in purifier waste typically color the waste bright blue (Prussian Blue), making it easy to detect in the field. However, cyanide analytical results did not indicate the presence of purifier wastes (i.e., detected cyanide concentrations in samples collected from the stained material ranged from 0.11 to 20 mg/kg, whereas cyanide concentrations in purifier wastes are typically in the 10,000 to 30,000 mg/kg range [Young and Theis, 1991]). The detected cyanide concentrations were also below the non-residential direct contact and non-residential soil-to-groundwater MSCs (1,900 and 200 mg/kg, respectively).

These observations are consistent with the historical characterization of bluish-green colored material observed onsite in 1981 and 1982. At that time, purifier waste and spent iron oxide were combined with tar decanter sludge, and conservatively managed as a characteristic hazardous waste for reactivity (Waste Code D003), although laboratory analytical results for waste characterization samples of this material did not exhibit the characteristic of reactivity. Additional blue-colored material was identified during excavation in 1990. As indicated in a June 15, 1990 letter from WCC to PADER, the blue-colored material underwent separate RCRA hazardous waste characterization sampling and analysis. Based on the laboratory analytical results, the blue-colored material did not exhibit the hazardous characteristic of reactivity and was therefore subsequently scraped and combined with other materials for offsite disposal as a non-hazardous waste.

Both the visual characterization information provided on the test pit/soil boring logs and the corresponding laboratory analytical data for cyanide support that there is no purifier and/or spent oxide wastes that would require remediation and that the material does not exhibit the hazardous characteristic of reactivity.

3.2.4 Soil Quality Evaluation

This section summarizes the quality of surface and subsurface soil at the Site based on the analytical results for the soil samples collected during the RI.

Approximately 540 soil samples were collected from the 150 soil borings and 145 test pits completed as part of the RI activities. Up to five soil samples were collected from a soil boring or test pit. As described in Section 3.1, soil samples were submitted for laboratory analysis for a combination of VOCs, SVOCs, inorganics including cyanide, pesticides, and PCBs.

For the purposes of evaluating the soil analytical results, the results have been compared to the following PADEP Statewide Heath Standards (SHS) established in Title 25 of the Pennsylvania Code Chapter 250, Administration of the Land Recycling Program:

1. The non-residential direct contact MSC for surface soil (if appliable).
2. The non-residential direct contact MSC for subsurface soil (if appliable).
3. The soil-to-groundwater MSCs for a non-residential used aquifer with TDS less than or equal to 2,500 ppm. The higher of the 100 X groundwater MSC or generic value is used. However, groundwater is not used for potable purposes at the Site and in the surrounding area, and groundwater impacts are generally limited to isolated areas of the perched groundwater zone.

These SHS are potentially applicable to the Site given the anticipated current and future site use. The property is currently zoned as industrial, and as indicated in the Cleanup Plan, the property will be deed restricted to non-residential use only. Please note, that the soil results are compared to VI screening values in Section 3.2.6.

A separate evaluation of the applicability of the Toxic Substances Control Act (TSCA) PCB regulations to PCBs identified in soil at the Site was submitted to the EPA on May 12, 2021, and EPA's response is provided in a July 8, 2021 letter to Arcadis (refer to Appendix K for copies of the evaluation and EPA's response). As indicated by EPA's response, EPA agrees that PCBs identified in soil samples collected at the Site, except in the southeast corner (Historic Tar Plains/Fill Area), are related to pre-April 1978 release(s) and are therefore not regulated under TSCA. Accordingly, PCC submitted to EPA a December 1, 2021 Self-Implementing Cleanup Notification for PCB Remediation Waste for material in this limited area at the southeast corner of the Site. EPA accepted the Self-Implementing Cleanup Notification in a January 5, 2022 approval letter. The Self-Implementing Cleanup Notification and EPA's approved letter are provided in Appendix K. PCB impacts outside the Historic Tar Plains/Fill Area will be addressed in accordance with the Cleanup Plan contained in Section 9 of this document.

To make the soil analytical results more manageable, the attached data tables (Tables 7 through 13) separate the soil analytical results into surface soils, unsaturated subsurface soils, and saturated subsurface soils. A soil sample was considered saturated if its elevation was below the higher of either: (1) the groundwater elevation encountered in the soil boring and test pit; or (2) the groundwater surface elevation from the highest potentiometric surface map (January 30, 2006 for Initial RI samples and March 2018 for SRI samples). Therefore, the saturated soil dataset also includes soil samples collected from the

anticipated capillary fringe area. Surface soil analytical results for detected constituents are presented in Tables 7 and 8, and surface soil sampling locations with results exceeding the non-residential direct contact MSCs are highlighted on Figure 18. Subsurface soil analytical results for detected constituents are presented in Tables 9 through 12 and subsurface soil sampling locations with constituent concentrations exceeding the non-residential direct contact MSCs are highlighted on Figure 19. Table 13 presents a statistical summary table for the soil analytical data.

Additionally, detail figures are provided for four areas of the Site where the sampling density is high (delineation areas) as follows:

- ***Area 1:*** *Eastern Part of Former Coal Storage Area*. Sampling locations PCTP-75 and PSSTP-04 where revisited and environmental impacts around these locations were delineated. Additionally, Arcadis installed four new monitoring wells in this area (MW-103, MW-108, MW-109, and MW-110).
- ***Area 2:*** *North/Northwest of Former Tar Storage Area*. Environmental impacts in soil around the Former Tar Storage Area have been delineated. Additionally, sampling locations PCTP-12 and PCTP-17 were revisited.
- ***Area 3:*** *South of Former Tar Storage Area*. Sampling locations PCTP-66 and TP-15 were revisited and environmental impacts around these locations were delineated.
- ***Area 4:*** *Former AST Farm East of Former Byproducts Operations*. Environmental impacts in soil near the former AST farm have been delineated. Sampling location TP-63 was revisits. Additionally, Arcadis installed three new monitoring wells in this area (MW-111 through MW-113).

The four above-identified areas are shown in Figure 20, and sampling locations with visual impacts in those areas are highlighted on Figures 21 through 24.

For the PSSTP- test pit series, please note that the sample IDs with the …A and …B suffix originate from the same sampling location and just represent different depth intervals (e.g., PSSTP-01A was a surface or shallow soil sample and PSSTP-01B was a subsurface sample collected from test pit sampling location PSSTP-01).

During the Initial RI activities, PS&S labelled the blind duplicate samples with “fake” sample IDs. Arcadis could not identify a key or table linking the duplicate samples with their associated parent samples. However, it appears that, in general, PS&S labelled the duplicate samples with a “2” in front of the parent sample ID (e.g., the parent for PCTP-260 (0.5) is PCTP-60 (0.5)). However, in some cases, the sample depth does not match that of the parent sample. In these cases, the blind duplicate data are not presented with a parent sample, the duplicate is not associated with a sample location in this RI Report’s figures, and the duplicate is counted as a separate sample but not a separate sampling location when presenting statistics[7]. Duplicate sample IDs without parent samples are limited to only the following: PCTP-214 (7.5), PCTP-236 (7), and TP-278 (9).

[7] During statistical discussions in this RI Report, duplicate samples with identified parents are counted as one sample.

3.2.4.1 Surface Soil Analytical Results

A total of 104 surface soil samples from 102 sampling locations[8] were collected and analyzed for VOCs, SVOCs, and inorganics. In addition, 93 samples were also collected for pesticides analysis, and 101 samples were collected for PCB analysis. For sampling locations S-138 through S-140, soil samples were only analyzed for PCBs (two samples from each boring for a total of six samples). Surface soil samples were generally collected throughout the Site, but with a higher density of samples from the Fuel Blending Area. Pesticides and PCBs were not detected in surface soil at concentrations greater than non-residential direct contact or soil-to-groundwater MSCs. Therefore, the discussion of surface soil analytical results below focuses on VOC, SVOCs, and inorganics. The locations of surface soils and associated MSC exceedances are shown on Figure 18.

Surface Soil Analytical Results for VOCs

No VOCs were detected in surface soil at concentrations greater than the non-residential direct contact MSCs. Other than benzene, no VOCs were detected in surface soil above the non-residential soil-to-groundwater MSC. Benzene was detected at a concentration greater than the 0.5 mg/kg soil-to-groundwater MSC at only four locations (PCSB-41R [0.5-2 feet bgs], PCTP-66 [0.5 feet bgs], PSSTP-22 [1-2 feet bgs], and S-113B [1-3 feet bgs]). The highest benzene concentration identified in surface soil was 29 mg/kg in the sample from PCTP-66 located in the southwest corner of the Site. As part of the SRI Activities, PCTP-66 was revisited and surrounded by delineation sampling locations. Benzene was not detected in the surface soil sample from PCTP-66R or surface soil samples from the four delineation sampling locations (S-119 through S-122). Benzene was detected at a concentration of 6.32 mg/kg in the sample from PCSB-41R located near the northern portion of the railroad tracks. Benzene concentrations at the other two locations (PCTP-22A in the center of the Site and S-113B in Area 2) were both below 1 mg/kg. VOCs in soil around the locations have been delineated.

Surface Soil Analytical Results for SVOCs

SVOCs were not detected at concentrations greater than the non-residential direct contact MSCs or the non-residential soil-to-groundwater MSCs in surface soil samples from 92 of 102 sampling locations. At the remaining 10 sampling locations, several PAHs common in urban/historic fill were generally detected at concentrations slightly higher than non-residential soil-to-groundwater MSCs. Of these 10 sampling locations, 8 sampling locations contained PAH concentrations exceeding the non-residential direct contact MSCs.

BaP concentrations exceeding direct contact MSCs were encountered at 9 of the 10 surface soil sampling locations where MSC exceedances were identified. 1,1-Biphenyl, BaA, BbF, dibenzofuran, indeno(1,2,3-cd)pyrene, and naphthalene were most frequently detected above MSCs (at three locations or more).

Multiple PAHs were identified at concentrations exceeding MSCs in surface soil collected from sampling locations PCTP-66 (0.5 feet bgs), PCTP-68 (0.5 feet bgs), S-151 (0.5-2), and S-163 (0.5-2 feet bgs). The highest PAH concentrations were identified at location PCTP-66 in the southwest corner of the Site. As indicated above, PCTP-66 was revisited during the SRI. 2-Methylnaphthalene, BaA, BaP, BbF, dibenz(a,h)anthracene, and naphthalene were detected in the surface soil sample collected from PCTP-

[8] Location count does not include sampling locations S-138 through S-140 where soil samples were only analyzed for PCBs.

66 at concentrations up to two orders of magnitude greater than non-residential direct contact MSCs. PAHs in soil around PCTP-66 were delineated during the SRI. Solidified tar was found on a cobble at PCTP-66R. Only 1,1-bipheny1[9], BaP, and BbF were detected at concentrations exceeding MSCs in the surface soil sample collected from PCTP-66R. Additionally, No SVOC were detected at concentrations exceeding MSCs from the delineation soil samples around PCTP-66.

PAH concentrations from PCTP-68, S-151, and S-163 are an order of magnitude less than those detected in PCTP-66, except naphthalene at PCTP-68. The location of PCTP-68 is in the center of the Site. S-151 is located near the northern portion of the railroad tracks, and S-163 is located in Area 2. PAHs in soil around these locations have been delineated.

Surface Soil Analytical Results for Inorganics

Inorganic constituents were not detected at concentrations greater than non-residential direct contact MSCs in surface soil from 81 of 102 sampling locations. Arsenic and lead were the most frequently detected inorganic constituents encountered at concentrations greater than MSCs in surface soil. Arsenic MSC exceedances in surface soil appear to be randomly distributed across the Site. Lead MSC exceedances in surface soil are mostly located in the Fuel Blending Area and at select locations in the center of the Site. Arsenic and lead impacts do not appear to be collocated with one another.

Arsenic concentrations in surface soil exceed the 61 mg/kg non-residential direct contact MSC at 13 sampling locations and the 29 mg/kg soil-to-groundwater MSC at 22 sampling locations. The highest arsenic concentrations are 170 mg/kg at PSSTP-30A, 120 mg/kg at PCTP-70, and 105 mg/kg at S-120. Outside these locations, arsenic concentrations are 100 mg/kg or less.

Lead concentrations in surface soil exceed the 1,000 mg/kg non-residential direct contact MSC at 12 sampling locations and the 450 mg/kg soil-to-groundwater MSC at 30 sampling locations. The highest lead concentrations were identified in surface soil samples collected from the Fuel Blending Area. The highest lead concentrations are 14,000 mg/kg at PCSB-36 (0.5 feet bgs), 6,200 mg/kg at PCSB-55 (0.5 feet bgs), and 5,400 mg/kg at PCSB-44 (0.5 feet bgs). Outside of the Fuel Blending Area, lead concentrations exceeding non-residential direct contact MSCs were only identified at two sampling locations: PCTP-78 (just west of the utility corridor at 1,100 mg/kg) and PSSTP-22 (near the middle of the Site at 1,130 mg/kg). Although lead concentrations may exceed the soil-to-groundwater MSCs, lead was not detected in any filtered groundwater samples at concentrations greater than the 5 µg/L residential and non-residential MSC.

Mercury is the only other inorganic that exceeds the 10 mg/kg soil-to-groundwater MSC. Mercury only exceeds the soil-to-groundwater MSC in surface soil collected from PCSB-06 (17 mg/kg), which is located in the Fuel Blending Area. Mercury was not identified in any groundwater samples at concentrations greater than the 2 µg/L residential and non-residential groundwater MSC.

3.2.4.2 Subsurface Soil Analytical Results

In total, subsurface soil samples from 283 sampling locations were analyzed for a combination of VOCs, SVOCs, inorganic constituents, pesticides, and PCBs. The sample count includes 39 sampling locations where both saturated and unsaturated soil samples were collected.

[9] The Initial RI soil sample collected from PCTP-66 was not analyzed for 1,1-biphenyl.

In the unsaturated zone, 77 subsurface soil samples from 75 sampling locations were collected and analyzed for VOCs, SVOCs, and inorganics. Of those 77 samples, 17 samples were also analyzed for pesticides and PCBs.

In the saturated zone, 354 subsurface soil samples from 249 sampling locations were collected and analyzed for VOCs and SVOCs. Of those 354 samples, 349 samples were also analyzed for metals, and 59 samples were analyzed for It pesticides and PCBs.

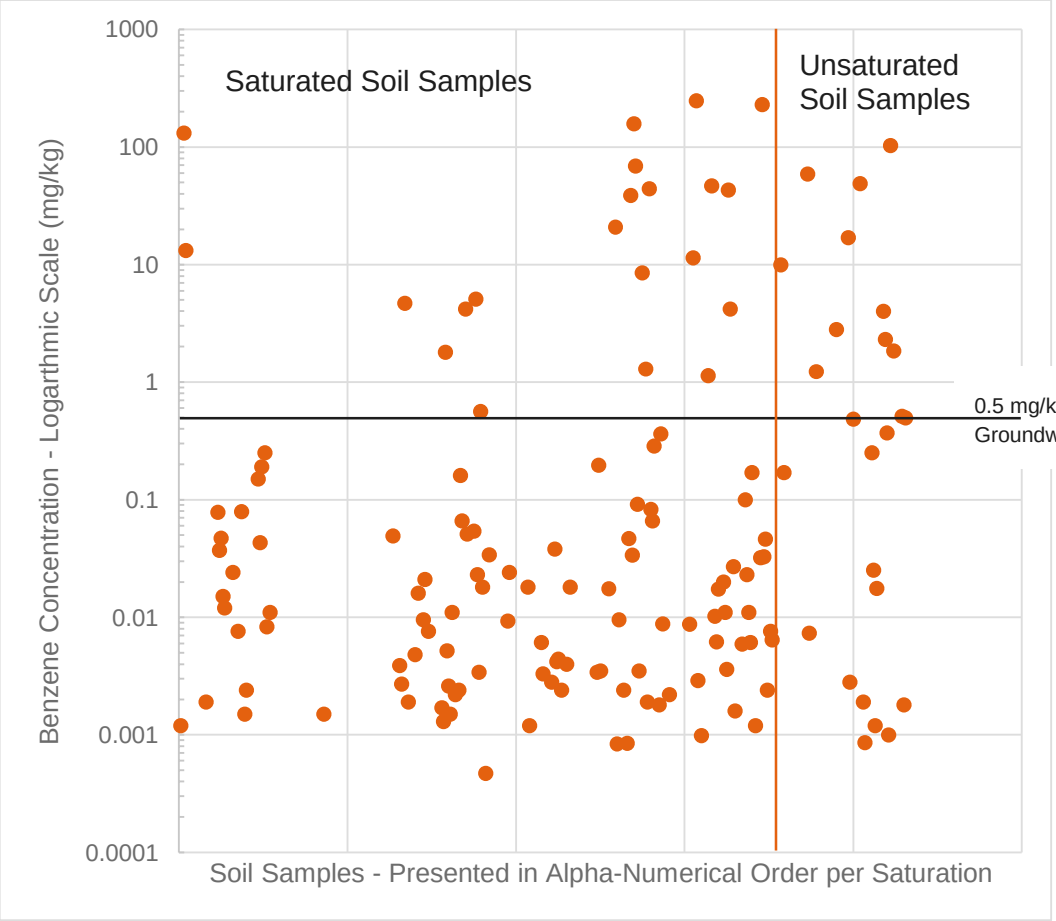
Similar to surface soil samples, pesticides and PCBs were not detected at concentrations exceeding the non-residential soil-to-groundwater MSCs. Therefore, the discussion of subsurface impacts below focuses on VOCs, SVOCs, and inorganic results exceeding non-residential soil-to-groundwater MSCs.

Subsurface Soil Analytical Results for VOCs

VOCs were not detected at concentrations exceeding the non-residential direct contact MSCs for subsurface soil in any of the subsurface soil samples collected from the Site; however, VOCs were detected at concentrations greater than the non-residential soil-to-groundwater MSCs in subsurface soil samples from 31 of 283 subsurface sampling locations. From these 31 subsurface soil sampling locations, several VOCs were detected at concentrations greater than the soil-to-groundwater MSCs in 11 unsaturated and 23 saturated soil samples (three sampling locations contained both unsaturated and saturated soil samples with VOCs exceeding the MSCs). Benzene was the only VOC detected in unsaturated soil at concentrations greater than the corresponding MSC. In saturated soil, benzene was detected at a concentration exceeding the MSC at each location that exhibited a VOC exceedance, except S-122 (Area 3B) and TP-33 (Former Coke Operations Area) where dichloromethane was the only VOC detected at a concentration greater than MSCs.

In general, subsurface soil sampling locations with higher concentrations of benzene also had higher concentrations of other VOCs. The highest benzene concentrations were detected in saturated soil in Area 4 (Former AST Farm East of Former Byproducts Operations): 247 mg/kg at S-155 (10-12 feet bgs), 230 mg/kg at TP-63 (8 feet bgs), and 157 mg/kg at S-125 (7 to 9 feet bgs). The highest benzene concentration in unsaturated soil is 103 mg/kg at S-161 from 5 to 7 feet bgs (also in Area 4). The distribution of benzene concentrations in unsaturated and saturated subsurface soil is shown on Figure 3-3 below. TP-63 had the most VOCs detected at concentrations greater than MSCs and S-155 had the second most VOCs detected at concentrations greater than MSCs. Viscous tar or oil-like material was observed at both locations (blebs at S-155; the quantity of viscous tar at TP-63 was not documented). TP-63 and S-155 are both located within Area 4. The viscous tar or oil-like material in Areas 4 has been delineated as part of the SRI Activities.

Figure 3-3: Distribution of Benzene Concentrations in Subsurface Soil Samples



Note: Data are presented in logarithmic scale on y-axis. Each sample where benzene was detected is represented by an orange dot. As illustrated above, most data are below the S-GW MSC for benzene of 0.5 mg/kg.

Chlorobenzene, dichloromethane, ethylbenzene, styrene, and toluene exceedances in saturated subsurface soil are collocated with benzene, except as noted above. Locations where each of these VOCs was found to exceed the corresponding soil-to-groundwater MSCs are summarized below:

- Chlorobenzene concentrations exceeded the 10 mg/kg MSC in subsurface soil samples from three sampling locations (S-125 [47.5 and 19 mg/kg], S-155 [40.7 mg/kg], and TP-63 [53 mg/kg]).
- Dichloromethane concentrations exceeded the 0.5 mg/kg MSC in subsurface soil samples from five sampling locations (PCTP-42 [0.91 mg/kg], PCTP-46 [1.2 mg/kg], S-122 [0.829 mg/kg], TP-15 [1.8 mg/kg], and TP-33 [3.2 mg/kg]).
- Ethylbenzene concentrations exceeded the 70 mg/kg MSC in subsurface soil samples from three sampling locations (PCTP-42 [180 mg/kg], S-155 [76 mg/kg], and TP-63 [140 mg/kg]).
- Styrene concentrations exceeded the 24 mg/kg MSC in subsurface soil samples from two sampling locations (MW-111 [29.5 mg/kg] and TP-63 [47 mg/kg]).

- The toluene concentration exceeded the 100 mg/kg MSC in the subsurface soil sample from one sampling location (TP-63 [140 mg/kg]).

No other VOCs were detected in subsurface soil at the Site at concentrations exceeding the non-residential soil-to-groundwater MSCs. Chlorobenzene, dichloromethane, ethylbenzene, styrene, and toluene were not detected in any groundwater samples at concentrations greater than applicable residential and non-residential groundwater MSCs.

Subsurface Soil Analytical Results for SVOCs

SVOCs were not detected at concentrations greater than the non-residential subsurface direct contact MSCs for soil samples collected from 244 of 283 sampling locations. From the remaining 41 subsurface soil sampling locations, the following SVOCs were detected at concentrations greater than the non-residential subsurface soil MSCs:

- Naphthalene was detected in subsurface soil samples collected from each of the 41 sampling locations at concentrations greater than the 77 mg/kg non-residential direct contact MSCs. Naphthalene was detected at concentrations two orders of magnitude or more above the non-residential MSCs in subsurface soil samples collected from the sampling locations MW-108, PCTP-12, PCTP-17, PCTP-46, PSSTP-04R, S-106, TP-15, and TP-63. Viscous tar or oil-like material was observed at each of these locations, and each of these locations is fully delineated in one of the four identified areas shown in Figures 21 through 24.
- 2-Methylnaphthalene was detected in subsurface soil samples collected from 18 sampling locations at concentrations greater than the 40 mg/kg non-residential direct contact MSCs. 2-Methylnaphthalene was detected at concentrations two orders of magnitude or more above the non-residential MSCs in subsurface soil samples collected from the sampling locations PCTP-12, PCTP-17, PCTP-46, and TP-63.
- 1,1-Biphenyl was detected in subsurface soil samples collected from 10 sampling locations[10] at concentrations greater than the 40 mg/kg non-residential direct contact MSCs. The highest detected 1,1-biphenyl concentrations are 331 mg/kg at S-106 from 2 to 4 feet bgs (unsaturated), 310 mg/kg at MW-108 from 5 to 7 feet bgs (unsaturated), and 301 mg/kg at PSSTP-04R at feet bgs (unsaturated).

Naphthalene was detected in subsurface soil at a concentration exceeding the direct contact MSC at each sampling location that exhibited a non-residential subsurface direct contact MSC exceedance. In total, naphthalene was detected at concentrations exceeding the non-residential subsurface direct contact MSCs in 14 unsaturated and 29 saturated soil samples. The subsurface soil sampling locations where results exceed the non-residential direct contact MSCs are shown on Figure 19. Naphthalene, 2-methylnaphthalene, and 1,1-biphenyl were detected in select groundwater samples at concentrations greater than applicable residential and non-residential groundwater MSCs.

SVOCs exceeded non-residential soil-to-groundwater MSCs in subsurface soil samples from 52 of 283 sampling locations (at 11 additional locations from where the subsurface direct contact MSCs were exceeded). 1,1-Biphenyl, 2-methylnaphthalene, BaP, and naphthalene were the most frequently detected SVOCs at concentrations greater than the non-residential soil-to-groundwater MSCs. The full list of

[10] 1,1-Biphenyl was only an analyte during the SRI activities. 1-1-Biphenyl was not analyzed for during the Initial RI activities.

SVOCs detected at concentrations greater than the non-residential soil-to-groundwater MSCs is presented in Table 3-5 of subsection 3.2.4.4.

In general, locations with higher naphthalene concentrations also had higher concentrations of other SVOCs. To evaluate the variability and magnitude of SVOC results, it is helpful to compare the total PAH concentrations[11]. Sampling locations exhibiting the highest total PAH concentrations are within the four delineation areas (Areas 1 through 4). Additionally, the SRI sampling results indicate that PAH concentrations at these locations are at least an order of magnitude less than the Initial RI results, indicating likely natural attenuation through degradation and other processes. Viscous tar or oil-like material was commonly observed at locations with elevated PAH concentrations.

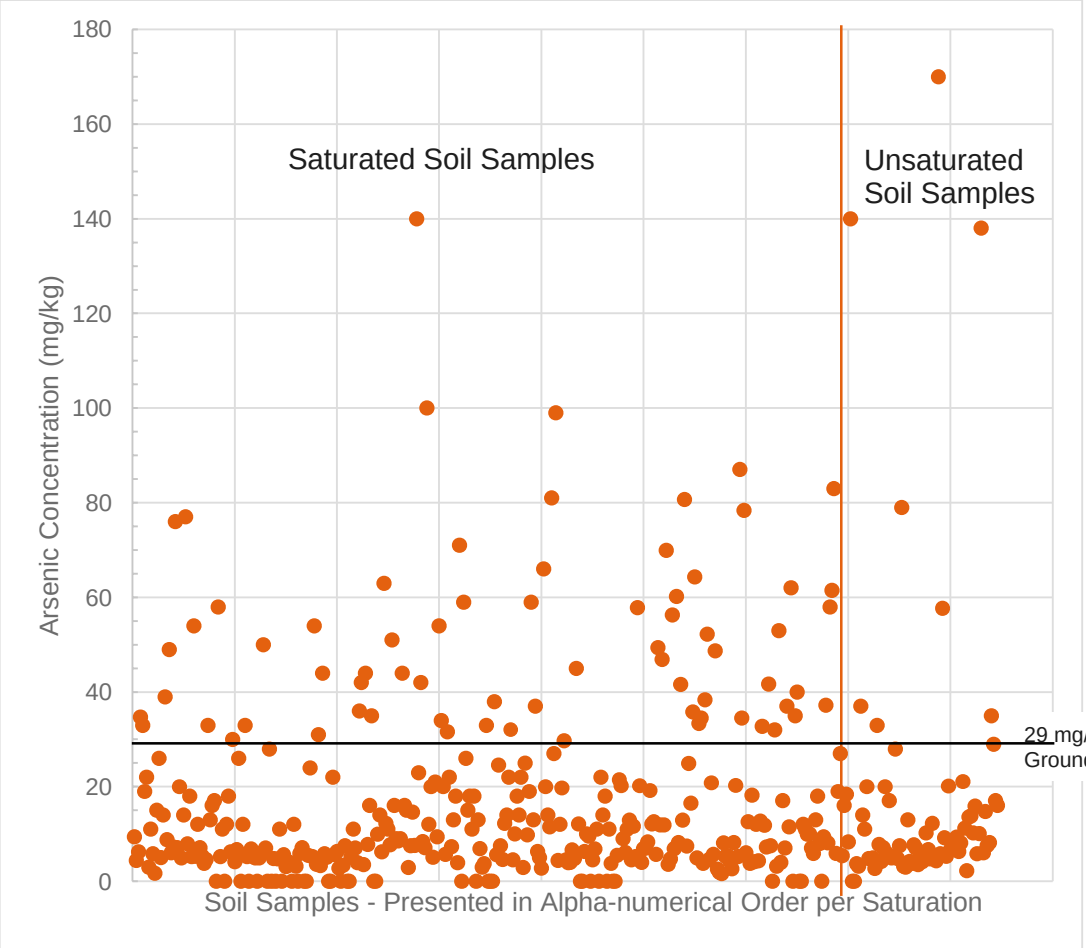
Subsurface Soil Analytical Results for Inorganics

Inorganics were not detected at concentrations exceeding the non-residential direct contact MSCs for subsurface soil in any of the subsurface soil samples collected from the Site; however, inorganic constituents were detected in subsurface soil samples from 107 of 281 sampling locations at concentrations greater than non-residential soil-to-groundwater MSCs. Similar to surface soil analytical results, arsenic and lead were the inorganic constituents most frequently detected in subsurface soil at concentrations greater than non-residential soil-to-groundwater MSCs. In addition, antimony, cyanide, mercury, nickel, and selenium were detected at select sampling locations (three or fewer separate sampling locations for each constituent) at concentrations greater than the non-residential soil-to-groundwater MSCs. Arsenic concentrations greater than non-residential soil-to-groundwater MSCs in subsurface soil are distributed across the Site. Lead concentrations greater than non-residential soil-to-groundwater MSCs in subsurface soil are mostly located in the Fuel Blending Area and at select locations elsewhere onsite. Arsenic and lead impacts do not appear to be collocated with one another. Antimony, cyanide, mercury, nickel, and selenium were detected at concentrations greater than non-residential soil-to-groundwater MSCs at subsurface sampling locations where lead was generally also detected at concentrations greater than the MSC, but these constituents are not collocated among themselves.

Arsenic concentrations exceed the 29 mg/kg soil-to-groundwater MSC at 76 sampling locations (8 unsaturated samples and 70 saturated samples). The highest detected arsenic concentrations are 170 mg/kg at S-105 from 2 to 4 feet bgs (unsaturated), 140 mg/kg at PCSB-30 at 2 feet bgs (unsaturated), and 140 mg/kg at PCTP-19 at feet bgs (saturated). The distribution of arsenic concentrations in subsurface soil is shown on Figure 3-4 below. Arsenic impacts appear to be randomly distributed across the Site.

[11] For purposes of this RI Report, total PAH is considered the sum of EPA 16 priority pollutant PAHs and 2-methylnaphthalene.

Figure 3-4: Distribution of Arsenic Concentrations in Subsurface Soil Samples



Note: Each sample is represented by an orange dot. As illustrated above, most data are below the S-GW MSC for arsenic of 29 mg/kg.

Lead concentrations exceed the 450 mg/kg soil-to-groundwater MSC at 58 sampling locations (14 unsaturated samples and 45 saturated samples). The highest detected lead concentrations are 62,000 mg/kg at PCTP-28 at 7 feet bgs (saturated), 26,000 mg/kg at PCSB-08 at 10.5 feet bgs (saturated), and 9,600 mg/kg at TP-44 at 4 feet bgs (unsaturated). PCTP-28 and PCSB-08 are located in the center of the Site. TP-44 is located in the Fuel Blending Area. Sampling locations PCTP-28 and TP-44 were revisited during the SRI. Lead concentrations at PCTP-28R did not exceed the soil-to-groundwater MSC. Lead concentrations at TP-44R exceeded the soil-to-groundwater MSC at one of three sampling intervals (2,840 mg/kg at 5-7 feet bgs). As discussed in Section 3.2.5, lead was not detected in any filtered groundwater samples at concentrations greater than the 5 µg/L residential and non-residential MSC.

Antimony, cyanide, mercury, nickel, and selenium exceedances are summarized below:

- Antimony concentrations exceeded the 27 mg/kg MSC in subsurface soil samples from three sampling locations (PCTP-09 [92 mg/kg], PCTP-12 [33 mg/kg], and PCTP-41[34 mg/kg]).

- Cyanide concentrations exceeded the 200 mg/kg MSC in subsurface soil samples from three sampling locations (PCTP-12 [340 mg/kg], PCTP-17 [670 mg/kg], and TP-64 [789 mg/kg]). No other inorganic constituents were detected in subsurface soil from TP-64 at concentrations greater than MSCs.
- The mercury concentration exceeded the 10 mg/kg MSC at one location (31 mg/kg at PCTP-68).
- The nickel concentration exceeded the 650 mg/kg MSC at one location (2,480 mg/kg at PSSTP-04R).
- The selenium concentration exceeded the 26 mg/kg MSC at one location (29 mg/kg at PCSB-30).

No other inorganic constituents were detected in subsurface soil at the Site at concentrations greater than the non-residential soil-to-groundwater MSCs. Cyanide (free), mercury, and selenium were not identified in any groundwater samples at concentrations greater than the applicable residential and non-residential MSC.

3.2.4.3 Comparison of Initial RI and SRI Results for Revisited Sampling Locations

Similar to the outcome of the visual characterization comparison between the Initial RI and SRI soil samples (which showed fewer visual impacts in SRI soil samples), laboratory analytical results show that most of the revisited sampling locations had lower concentrations than those identified at the original sampling locations, sometimes by an order of magnitude or more. Therefore, the Initial RI data may be biased (i.e., potentially focusing on small blebs or pockets of impacted material and not representing overall conditions at the sampling location). Considered alone, the Initial RI data likely over-predicts the magnitude of Site-related impacts as the impacts were often not reproduced in the revisited sampling locations. However, the site-wide distributions of soil impacts are generally consistent between the Initial RI and SRI results, and the overall site model is unchanged by the SRI data.

The differences in concentrations from the Initial RI and SRI Activities are potentially due to a combination of factors, including survey discrepancies, location adjustments because of access issues (e.g., due to vegetation or terrain), natural attenuation/degradation processes, and selection of soil samples by different onsite geologists (different bias). Additionally, Initial RI concentrations may be higher than SRI concentrations because the majority of the initial RI subsurface soil samples were collected from test pits instead of borings, and test pits may expose more potentially impacted soil for sample selection.

3.2.4.4 Soil Investigation Conclusion

In total, 104 surface and more than 430 subsurface samples were collected for laboratory analysis to characterize the nature and extent of Site-related impacts. The number and density of samples is more than sufficient to complete delineation of the Site COCs and advance the project into cleanup.

No surface or subsurface samples exceed the non-residential direct contact or soil-to-groundwater MSCs for pesticides and PCBs. Therefore, cleanup activities will be focused on areas where the VOC, SVOC, and inorganic concentrations exceed MSCs.

Constituents in surface soil exceeding non-residential direct contact MSCs are limited to select SVOCs, arsenic, and lead. The SVOC and arsenic concentrations found in surface soil are typical of urban/historic fill, except SVOC results at surface soil sampling location PCTP-66 which was resampled during the SRI. SVOC impacts in surface soil around PCTP-66 have been delineated. SVOC impacts in surface soil at

PCTP-66 are collocated with solidified tar or tar-like material. Surface soil containing lead concentrations greater than non-residential direct contact MSCs are in the Fuel Blending Area and at two locations in the center of the Site. COCs in surface soil are listed in Table 3-4 below.

Table 3-4: Soil Constituents in Surface Soil Exceeding Non-Residential Direct Contact MSCs

Analyte	CAS Number	Direct Contact Exceedance Frequency
Semi-Volatile Organic Compounds		
2-Methylnaphthalene	91-57-6	1/104
Benz(a)anthracene	56-55-3	3/104
Benzo(a)pyrene	50-32-8	3/104
Benzo(b)fluoranthene	205-99-2	8/104
Benzo(k)fluoranthene	207-08-9	2/104
Chrysene	218-01-9	1/104
Dibenz(a,h)anthracene	53-70-3	3/104
Indeno(1,2,3-cd)pyrene	193-39-5	3/104
Naphthalene	91-20-3	3/104
Metals		
Arsenic	7440-38-2	13/104
Lead	7439-92-1	12/104

VOCs and inorganics were not identified in subsurface soil at concentrations exceeding non-residential direct contact MSCs for subsurface soil. 1,1-Biphenyl, 2-methylnaphthalene, and naphthalene were the only SVOCs detected in subsurface soil at concentrations exceeding non-residential direct contact MSCs, as listed in Table 3-5.

Table 3-5: Soil Constituents in Subsurface Soil Exceeding Non-Residential Direct Contact MSCs

Analyte	CAS Number	Direct Contact Exceedance Frequency
Semi-Volatile Organic Compounds		
1,1-Biphenyl	92-52-4	11/150
2-Methylnaphthalene	91-57-6	18/431
Naphthalene	91-20-3	43/431

The subsurface soil sampling locations exhibiting the highest VOC and SVOC concentration also have the highest benzene and naphthalene concentrations. The highest VOC concentrations in subsurface soil are in Area 4 and the highest SVOC concentrations in subsurface soil are in the four delineation areas (Areas 1 through 4). Elevated VOC and SVOC concentrations are typically collocated with visual impacts (e.g., pockets of viscous tar, oil-like material, and solidified tar). VOC and SVOC concentrations have been delineated. Similar to surface soil findings, arsenic and lead are the primary inorganic COCs in subsurface soil. Additionally, groundwater is characterized throughout the Site (as discussed in Section 3.2.5), and many of the constituents detected in soil at concentrations greater than the S-GW MSC were not detected in groundwater samples at concentrations greater than applicable residential and non-

residential groundwater MSCs. Furthermore, groundwater impacts are generally limited to isolated areas in the perched groundwater zone, and there is a limited presence of site-related constituents in the underlying deep groundwater aquifer, as discussed in Subsection 3.2.5.

This includes the following constituents: chlorobenzene, dichloromethane, ethylbenzene, styrene, toluene, 1,1-biphenyl, 2-methylnaphthalene, 4-methylphenol, anthracene, fluoranthene, fluorene, phenanthrene, phenol, pyrene, cyanide, lead, mercury, and selenium. The COCs in surface and subsurface soil are identified in Table 3-6 below.

Table 3-6: Soil Constituents Exceeding Non-Residential Soil-to-Groundwater MSCs

Analyte	CAS Number	S-GW Exceedance Frequency	Concentration in GW Above Applicable GW MSCs (discussed in Section 3.2.5)
Volatile Organic Compounds			
Benzene	**71-43-2**	**36/530**	**Yes**
Chlorobenzene	108-90-7	4/530	No
Dichloromethane	75-09-2	5/530	No
Ethylbenzene	100-41-4	3/529	No
Styrene (Monomer)	100-42-5	2/470	No
Toluene	108-88-3	1/532	No
Semi-Volatile Organic Compounds			
1,1-Biphenyl	**92-52-4**	**28/168**	**Yes**
2-Methylnaphthalene	**91-57-6**	**30/535**	**Yes**
4-Methylphenol	106-44-5	1/296	No
Anthracene	120-12-7	15/535	No
Benz(a)anthracene	**56-55-3**	**15/535**	**Yes**
Benzo(a)pyrene	**50-32-8**	**39/535**	**Yes**
Benzo(b)fluoranthene	**205-99-2**	**22/535**	**Yes**
Benzo(g,h,i)perylene	**191-24-2**	**13/535**	**Yes**
Benzo(k)fluoranthene	**207-08-9**	**6/535**	**Yes**
Carbazole	**86-74-8**	**18/535**	**Yes**
Chrysene	**218-01-9**	**18/535**	**Yes**
Dibenz(a,h)anthracene	**53-70-3**	**2/535**	**Yes**
Dibenzofuran	**132-64-9**	**16/535**	**Yes**
Fluoranthene	206-44-0	8/535	No
Fluorene	86-73-7	4/535	No
Naphthalene	**91-20-3**	**54/535**	**Yes**
Phenanthrene	85-01-8	4/535	No
Phenol	108-95-2	2/535	No
Pyrene	129-00-0	6/535	No
Metals			
Antimony	**7440-36-0**	**3/527**	**Yes**
Arsenic	**7440-38-2**	**101/527**	**Yes**

Analyte	CAS Number	S-GW Exceedance Frequency	Concentration in GW Above Applicable GW MSCs (discussed in Section 3.2.5)
Cyanide	57-12-5	3/333	No
Lead	7439-92-1	89/527	No
Mercury	7439-97-6	2/525	No
Nickel	**7440-02-0**	**1/527**	**Yes**
Selenium	7782-49-2	1/527	No

Notes: S-GW indicates the soil-to-groundwater MSCs for a non-residential used aquifer with TDS less than or equal to 2,500 ppm; GW = groundwater.

3.2.5 Groundwater Quality Evaluation

This section summarizes the groundwater quality at the Site based on analytical results of groundwater samples collected from monitoring wells and hydropunch sampling locations during the RI.

During the Initial RI activities, groundwater samples were collected from 33 monitoring wells and 7 hydropunch locations. The 33 monitoring wells were sampled in November 2005 and January/February 2006 for VOCs, SVOCs, total metals, dissolved metals, pesticides, and PCBs, except PCMW-08S which was only sampled in November 2005. Groundwater samples collected from the hydropunch locations were analyzed for VOCs, SVOCs, and total metals.

During the monitoring well integrity survey performed as part of the SRI Activities, Arcadis located 23 of the 33 Initial RI monitoring wells (wells identified by the prefix “PCMW-”) as shown on Initial RI site maps, plus two of the nine pre-2003 monitoring wells (wells identified with the ID “MW-”). As listed in Table 3-3 (Subsection 3.1.2.1), Arcadis installed four monitoring wells to replace Initial RI monitoring wells that could not be located in 2018. Arcadis also installed nine additional monitoring wells in areas where groundwater was not sufficiently characterized by the Initial RI monitoring well network, including Areas 1 and 4 where the most impacted soils were observed.

During the SRI Activities, Arcadis sampled groundwater from 23 existing wells (including two wells of unknown construction) and 13 new SRI monitoring wells for a combination of VOCs, SVOCs, total inorganics, dissolved inorganics, total cyanide, free cyanide, TDS, pesticides, and PCBs.

The groundwater analytical results have been compared to the PADEP Non-Residential MSCs for Used Aquifers containing TDS ≤ 2,500 mg/L. These MSCs are applicable to the Site given the anticipated current and future site use for commercial or industrial purposes. Groundwater is not used for potable purposes at the Site and in the surrounding area. For documentation purposes, the groundwater analytical results are also compared in this Section to the PADEP Residential MSCs for Used Aquifers containing TDS ≤ 2,500 mg/L. Please note that the groundwater results are compared to VI screening values in Section 3.2.6.

Groundwater analytical results for hydropunch locations are presented in Table 14. Groundwater analytical results for monitoring wells are presented in Tables 15 through 17. A statistical summary of groundwater analytical data for samples collected from the monitoring wells is presented in Table 18.

Additionally, groundwater analytical results exceeding the above-identified MSCs are shown in Figures 25 and 26.

During the Initial RI activities, PS&S labelled the blind duplicate samples with “fake” sample IDs. Arcadis could not identify a key or table linking the duplicate samples with their associated parent samples. However, it appears that, in general, PS&S labelled the duplicate samples with a “2” in front of the parent sample ID (e.g., the parent for PCMW-214D (11/9/05) is PCMW-14D (11/9/05)). However, in some cases, the duplicate ID does not indicate if the sample was collected from the deep or shallow well in the cluster. In these cases, the blind duplicate data are not included in the discussion below. Duplicate sample IDs without parent samples are limited to only the following: PCMW-211 (2/2/2006) and PCMW-212 (2/1/2006). However, results for these duplicate samples are included in the statistics in Table 18.

3.2.5.1 Hydropunch Groundwater Sampling Results

In general, hydropunch samplers were advanced in the areas where soil impacts were observed in the Initial RI. The analytical results for groundwater samples collected from hydropunch locations are summarized below:

- VOCs and SVOCs were not detected in any of the hydropunch groundwater samples at concentrations exceeding the MSCs, except the sample from PCHP-03 which is located in the center of the Site. At PCHP-03, benzene was detected at a concentration of 290 µg/L vs the 5 µg/L on-residential MSC and select PAHs were detected at concentrations up to 6.3 µg/L (BaA at 6 µg/L, BaP at 4.6 µg/L, BbF at 6.3 µg/L, benzo(g,h,i) perylene at 2.8 µg/L, benzo(k)fluoranthene at 1.8 µg/L, chrysene at 5.1 µg/L, and indeno(1,2,3-cd)pyrene at 2.5 µg/L vs. non-residential MSCs of 4.9, 0.2, 1.2, 0.26, 0.55, 1.9, and 2.3 µg/L, respectively). No other VOCs or SVOCs were detected above MSCs in the hydropunch groundwater samples. Groundwater impacts around PCHP-03 have been delineated by PCHP -01, PCHP-06, PCHP-07, PCMW-14S/MW-101 and PCMW-15S.
- Amenable cyanide was not detected in any of the hydropunch groundwater samples at concentrations exceeding the MSCs.
- Metals were detected at concentrations exceeding the MSCs in unfiltered groundwater samples collected from 6 of the 7 hydropunch locations. Elevated metal concentrations are likely the result of the sample collection method. Hydropunch samples are not collected using standard low-flow methods through a developed monitoring well and typically have very high turbidity biasing metal results to be high due to entrained solids.

3.2.5.2 Shallow Groundwater Sampling Results

A total of 35 monitoring wells are screened in the shallow groundwater zone located within the historic fill unit, including 20 wells installed during the Initial RI activities, 13 wells installed during the SRI activities, and two wells installed sometime before 2003 (i.e., those two wells were found and sampled in 2018). Except for the observation of emulsified petroleum in PCMW-05 during the Initial RI, NAPL was not encountered in any shallow groundwater monitoring wells. This emulsion was not observed during the SRI.

During both the Initial RI and SRI, pesticides and PCBs were not detected at concentrations greater than the applicable MSCs (i.e., residential or non-residential MSCs for used aquifers with TDS ≤2,500 mg/L) in

any of the groundwater samples collected from the shallow monitoring wells. Therefore, the discussion of shallow groundwater analytical results below focuses on VOC, SVOCs, and inorganics. The shallow groundwater analytical results are summarized below.

Shallow Groundwater Sampling Results for VOCs

When combining the Initial RI and SRI data, VOCs were not detected at concentrations greater than the MSCs in 28 of the 35 shallow groundwater monitoring wells. SRI groundwater analytical results indicate that groundwater quality has improved onsite since the Initial RI investigation, demonstrated by the decreasing benzene concentrations. VOCs were detected above MSCs at the following locations:

- *PCMW-10S, PCMW-14S, PCMW-15S, & PCMW-17S* – During the Initial RI, benzene was detected in groundwater at concentrations greater than the 5 µg/L non-residential and residential MSCs in each of these four monitoring wells. However, benzene was not detected above the 5 µg/L MSCs in groundwater collected from these wells (or MW-14S replacement well MW-101) during the SRI.
- *MW-107* - Methyl-tert-butyl ether (MTBE) was detected in the May 30, 2018 groundwater sample from this well at a concentration of 20.7 µg/L which is slightly greater than the 20 µg/L residential and non-residential MSC. MTBE was not evaluated in groundwater samples collected during the Initial RI groundwater samples and is not considered to be related to Site operations.
- *MW-111* – Based on the SRI results, the highest benzene concentration (686 µg/L) was detected in a groundwater sample collected from this well on October 4, 2019. Benzene was not detected above laboratory detection limits in groundwater downgradient from MW-111 (i.e., MW-112 or MW-113 to the east of MW-111) during the same event. Therefore, benzene groundwater impacts are limited to the vicinity of MW-111.
- *MW-5* –TCE was detected in the March 19, 2018 groundwater sample from this well at a concentration of 6.1 µg/L which is slightly higher than the 5 µg/L residential and non-residential MSC. TCE was not identified in the Initial RI groundwater samples collected from any of the wells at the Site. TCE was not detected elsewhere onsite during the March 2018 event.

Shallow Groundwater Sampling Results for SVOCs

SVOCs were not detected in 29 of the 35 shallow groundwater monitoring wells at concentrations greater than the MSCs. SVOCs were detected above MSCs at the following locations:

- *MW-102* – Bis(2-ethylhexyl) phthalate was detected in the May 31, 2018 groundwater sample from this well at a concentration of 11.3 µg/L which is greater than the 6 µg/L residential and non-residential MSC. However, since bis (2-ethylhexyl) phthalate was not detected in the duplicate sample collected from this well, the detection is potentially indicative of laboratory contamination. Groundwater samples were not collected from this well on any other date.
- *MW-107* – Multiple low-level PAHs were detected in the May 30, 2018 groundwater sample from this well at concentrations slightly greater than one or both groundwater MSCs. Low-level PAHs are typically associated with urban/historic fill such as the fill observed onsite. BbF was identified in this well at the highest concentration of any PAHs exceeding MSCs (1.7 µg/L vs. 1.2 µg/L non-residential MSC). BaP and benzo(g,h,i)perylene were also detected above the non-residential MSCs (1.2 and 0.95 µg/L vs. MSCs of 0.2 and 0.26 µg/L, respectively). Groundwater samples were not collected from this well on any other date.

- *MW-111* – The highest PAH concentrations in groundwater were detected in the October 4, 2019 groundwater sample collected from this well. The two PAHs with the highest concentrations at this well were naphthalene (973 µg/L vs. 100 µg/L non-residential MSC) and carbazole (189 µg/L vs. 140 µg/L non-residential MSC). PAHs were not detected above MSCs in groundwater downgradient from MW-111 (i.e., MW-112 or MW-113 to the east of MW-111).
- *PCMW*-05 – 2-Methylnaphthalene was detected in the November 2, 2005 groundwater sample from this well at a concentration of 34 µg/L, which is greater than the 26 µg/L non-residential MSC. The 2-methylnaphthalene concentration was 8.1 µg/L in the January 31, 2006 groundwater sample from this well, and 2-methylnaphthalene was not detected above the 1.0 µg/L laboratory reporting limit in the March 23, 2018 groundwater sample from this well.
- *PCMW-16S* – Multiple low-level PAHs were detected in the February 1, 2006 groundwater sample from PCMW-16S at concentrations slightly greater than one or both groundwater MSCs. PAHs were not detected at concentrations greater than MSCs in the replacement monitoring well for PCMW-16S (MW-105) sampled on May 30, 2018.
- *PCMW-17S* – 2-Methylnaphthalene was detected in the February 3, 2006 groundwater sample from this well at a concentration of 48 µg/L which is greater than the 26 µg/L non-residential MSC. The 2-methylnaphthalene concentration was 20 µg/L in the November 11, 2005 groundwater sample from this well, and 2-methylnaphthalene was not detected above the 1.0 µg/L laboratory reporting limit in the March 22, 2018 groundwater sample from this well.

Shallow Groundwater Sampling Results for Inorganics

Inorganics that are commonly present in urban/historic fill or considered naturally occurring minerals were detected in the groundwater samples from across the Site at concentrations exceeding the MSCs[12]. Some of the samples collected were turbid and contained suspended particulates that are the likely source of the elevated metals concentrations. For this reason, groundwater samples collected from 27 of the 35 shallow groundwater monitoring wells (18 wells during the Initial RI only, 7 wells during the SRI only, and 2 wells during both the Initial RI and SRI) were also filtered in the laboratory and analyzed for dissolved inorganic constituents. After groundwater sample filtration, only six inorganic constituents (antimony, arsenic, manganese, and nickel) were identified in the shallow groundwater at concentrations greater than MSCs. The total and dissolved laboratory analytical results for constituents exceeding MSCs are summarized below:

- Antimony was detected at concentrations slightly exceeding the 6 µg/L residential/non-residential MSC in three unfiltered and one filtered groundwater samples collected from the shallow groundwater monitoring wells. This includes unfiltered groundwater samples from PCMW-07 (6.4 µg/L on November 3, 2005), PCMW-08S (9.9 µg/L on March 22, 2018), and PCMW-13S (6.4 µg/L on November 9, 2005) and a filtered groundwater sample from PCMW-11S (7.8 µg/L on November 7, 2005). As indicated above, each groundwater sample containing antimony exceeding the MSC was collected from a separate groundwater monitoring well.
- Arsenic, a common groundwater constituent in urban/historic fill, was detected at concentrations greater than the 10 µg/L MSC in unfiltered groundwater samples collected from 9 of the 35 shallow

[12] Note that there is no difference between residential and non-residential MSCs for the detected inorganics.

groundwater monitoring wells (concentrations ranging from 12 to 160 µg/L). Dissolved arsenic was only detected at concentrations greater than MSCs in filtered groundwater collected from the two monitoring wells exhibiting the highest concentration of total arsenic, including PCMW-08S (21 µg/L on November 3, 2005) and PCMW-19S (11 µg/L on November 14, 2005).

- Total cyanide was identified at concentrations exceeding the 200 µg/L residential/non-residential MSC for free cyanide in SRI groundwater samples collected from three shallow groundwater monitoring wells, including MW-104 (670 µg/L on May 30, 2018), MW-113 (an estimated 380 µg/L October 4, 2019), and PCMW-15S (an estimated 210 µg/L March 20, 2018). There is no MSC for total cyanide. Initial RI groundwater samples were not analyzed for total cyanide. A July 27, 2018 groundwater sample from PCMW-15S was analyzed for free cyanide, and the free cyanide concentration was 9.0 µg/L which is two orders of magnitude below the 200 µg/L MSC, indicating that only a small fraction of total cyanide is free (i.e., bioavailable).
- Lead was identified at concentrations exceeding the 5 µg/L residential/non-residential MSC in groundwater samples from 21 of the 35 shallow monitoring wells. Lead concentrations were generally consistent between Initial RI samples and SRI samples. Lead was not detected in the filtered groundwater samples at concentrations greater than the MSC, indicating that lead impacts are related to turbidity.
- Nickel was detected at concentrations exceeding the 100 µg/L residential/non-residential MSC in groundwater samples (unfiltered or filtered) from only one well (PCMW-05, which is in the former Fuel Blending Area). Nickel was identified in three of four unfiltered samples from PCMW-05 (250 µg/L on January 1, 2006, 450 µg/L on March 23, 2018, and 524 µg/L on May 30, 2018) and one filtered sample from PCMW-05 (210 µg/L on January 31, 2006). This indicates that nickel impacts in groundwater are isolated.

Additionally, naturally occurring mineral constituents, manganese and zinc, were detected in groundwater at concentrations greater than MSCs. Manganese was detected at concentrations most frequently above the MSCs (in 25 of 28 monitoring wells sampled for total manganese and 8 of 9 wells sampled for dissolved manganese[13]). Zinc was detected at concentrations greater than MSCs in one of the 30 monitoring wells sampled for zinc (PCMW-05), but dissolved zinc was not detected above MSCs.

3.2.5.3 Deep Groundwater Sampling Results

A total of 13 monitoring wells were installed below the silt and clay confining unit and screened in the deep groundwater zone (wells PCMW-08D through PCMW-20D). NAPL was not encountered in any deep groundwater monitoring wells. Similar to the groundwater analytical results for the shallow monitoring wells, pesticides and PCBs were not detected at concentrations greater than the residential or non-residential MSCs, except dieldrin (an organochloride insecticide[14]) at PCMW-17D which was detected at a concentration of 0.046 µg/L in the March 22, 2018 groundwater sample (greater than the 0.041 µg/L residential MSC but less than the 0.17 µg/L non-residential MSC). Dieldrin was also detected in the

[13] Initial RI groundwater samples were not analyzed for manganese which is why the count of sampled wells differs from the previous discussion.
[14] Dieldrin was produced as an insecticide from the 1950s to 1970, and was widely used as pesticide for corn, cotton, and citrus crops. Dieldrin was also used to control termites until 1989.

March 22, 2018 groundwater sample collected from PCMW-16D at 0.038 µg/L. Dieldrin was not detected in any groundwater samples collected during the Initial RI, and it was not detected in groundwater samples collected from monitoring wells located in the primary production area of the Site or at the downgradient point-of-compliance wells. Therefore, it is likely that the presence of dieldrin in deep groundwater at the two wells identified above is due to background conditions and not site related. Additionally, there is no documented use or production of dieldrin in former Site operations. A discussion of the VOCs, SVOCs, and inorganics detected in the deep groundwater aquifer is below.

Deep Groundwater Sampling Results for VOCs

VOCs were not detected in 12 of 13 deep groundwater monitoring wells at concentrations greater than the MSCs. Tetrachloroethene was the only VOC identified in the deep groundwater samples at a concentration greater than its corresponding residential/non-residential MSC (5 µg/L) and only during the initial RI. Tetrachloroethene was detected in the November 8, 2005 groundwater sample from PCMW-11D at a concentration of 37 µg/L. Tetrachloroethene was detected at a concentration of 4 µg/L when well PCMW-11D was resampled in 2006. PCMW-11D could not be located for resampling during the SRI. Tetrachloroethene was not identified above 5 µg/L in any of the other deep groundwater samples. Based on Site history and soil analytical results, tetrachloroethene is not a Site-related constituent.

Deep Groundwater Sampling Results for SVOCs

SVOCs were not detected in 11 of 13 deep groundwater monitoring wells at concentrations greater than the MSCs. SVOCs were detected above MSCs at the following locations:

- *PCMW-09D* – BaA, BaP, BbF, and chrysene were detected in the January 31, 2006 groundwater sample from this well at concentrations slightly greater than the corresponding residential and/or non-residential groundwater MSCs. Of these four PAHs, BbF was detected at the highest concentration at 2.5 µg/L (the corresponding non-residential MSC is 1.2 µg/L). The four PAHs were not detected above laboratory detection limits in the previous groundwater sample from this monitoring well, which was collected approximately three months earlier, on November 7, 2005. Comparing groundwater gauging records from October 31, 2005 to December 30, 2005 reveals that approximately 6.5 feet of sediment filled in the screened interval between the two events likely blocking the portion of the screened interval within the transmissive sand and gravel unit. The lack of water produced by PCMW-09D during the January 31, 2006 sampling event required the field team to collect the sample with a bailer. That sample was very turbid (130 NTUs) compared to the sample collected from the well using low-flow techniques[15] during the November 7, 2005 sampling event (assumed 0 NTUs as the sampling log indicates -4.4 NTUs). Therefore, the November 7, 2005 sample from PCMW-09D is reliable while the January 31, 2006 sample from this well is not. PCMW-09D could not be located for resampling during the SRI.
- *PCMW-16D* – 2,4-Dinitroluene was detected in the March 19, 2018 groundwater sample from this well at a concentration of 13.3 µg/L, which is greater than the 2.1 µg/L residential and 8.8 µg/L non-residential MSCs. This constituent was not detected in any of the other SRI groundwater samples. Initial RI groundwater samples were not analyzed for 2,4-dinitrolouene. The presence of 2,4-dinitroluene in groundwater appears to be isolated to this area near the intersection of Orthodox

[15] PCMW-09D sustained a purge rate of 300 milliliters per minute with approximately 0.3 feet of drawdown during the November 7, 2005 sampling event.

Street and Casper Street. The deep zone potentiometric surface map in the vicinity of PCMW-16D indicates that groundwater is flowing primarily parallel to Orthodox Street with a component of groundwater flow directed easterly to the Site from offsite. Therefore, it is not likely that the groundwater impacts from PCMW-16D are Site-related but are likely due to background conditions. Additionally, 2,4-dinitroluene is not related to former Site operations.

Deep Groundwater Sampling Results for Inorganics

Similar to the analytical results for groundwater samples collected from the shallow monitoring wells, inorganics that are commonly present in urban fill or considered naturally occurring minerals were detected at concentrations exceeding the MSCs in groundwater samples collected from the deep wells across the Site. Some of the samples collected were turbid and contained suspended particulates that are the likely source of the elevated metals. For this reason, samples from the deep groundwater monitoring wells were also filtered in the laboratory and analyzed for dissolved inorganic constituents. After groundwater sample filtration, only arsenic and manganese were identified in the deep groundwater at concentrations greater than MSCs. Therefore, beryllium, lead, and cyanide in the deep groundwater zone appear to be attributed to suspended particulates. The total and dissolved laboratory analytical results for inorganic constituents exceeding MSCs are summarized below:

- Arsenic was detected at concentrations greater than the 10 µg/L MSC in unfiltered groundwater samples collected from 6 of 13 deep groundwater monitoring wells. Dissolved arsenic was only detected at concentrations greater than the 10 µg/L MSC in one filtered groundwater sample (i.e., the November 14, 2005 sample from PCMW-20D at a concentration of 11 µg/L).
- Beryllium and lead were detected at concentrations greater than their corresponding MSCs (4 µg/L and 5 µg/L, respectively) in the January 31, 2006 groundwater sample from PCMW-09D (concentrations of 5.1 µg/L and 170 µg/L, respectively). Similar to PAHs at PCMW-09D, neither beryllium nor lead was detected in the November 7, 2005 groundwater sample collected from PCMW-09D, and therefore the presence of these inorganics is likely associated with the high turbidity of the January 31, 2006 sample. Beryllium and lead were not detected in the filtered groundwater samples from any of the deep groundwater monitoring wells.
- Total cyanide was identified at a concentration exceeding the 200 µg/L residential/non-residential MSC for free cyanide in groundwater from only one deep monitoring well (350 µg/L in the March 22, 2018 groundwater sample collected from PCMW-10D). There is no MSC for total cyanide. Initial RI groundwater samples were not analyzed for total cyanide. A July 27, 2018 groundwater sample from PCMW-10D was analyzed for free cyanide, and the free cyanide concentration was 4.1 µg/L. Additionally, free cyanide was detected in the May 30, 2018 groundwater sample from PCMW-16D at an estimated concentration of 9.1 µg/L (18 µg/L in the duplicate sample from the well).
- Manganese, a naturally occurring mineral constituent, was detected at concentrations greater than the 300 µg/L MSC in groundwater samples collected from 8 of the 13 monitoring wells. Dissolved manganese was only detected at a concentration greater than MSCs in the March 28, 2019 filtered groundwater sample from PCMW-16D (3,130 µg/L).

3.2.5.4 Groundwater Investigation Conclusions

In addition to the extensive groundwater investigation performed from April 1985 through November 1998, the RI groundwater investigation provides sufficient data for evaluating groundwater quality across the Site. Groundwater analytical results indicate that groundwater quality at the Site is relatively unimpacted by former site operations and that source material is not present onsite. Select VOCs and SVOCs were identified in groundwater samples from 13 of 50 monitoring wells at concentrations exceeding applicable MSCs. However, the results indicate that VOCs and SVOCs were: (1) detected at concentrations within an order of magnitude of MSCs in the most-recent monitoring event in all but one location (MW-111); and (2) detected at much lower concentrations during the SRI then the Initial RI at the same well or a replacement well. The extent of VOCs and SVOCs in shallow groundwater downgradient from MW-111 is delineated by the samples from downgradient monitoring wells (MW-112 and MW-113, both located east of MW-111). Based on groundwater data from point-of-compliance wells, COCs are not migrating offsite at concentrations above residential MSCs.

Inorganic constituents were identified at concentrations exceeding applicable groundwater MSCs. However, these constituents are commonly present in urban/historic fill or considered naturally occurring minerals and are not necessarily attributed to former Site operations. Additionally, most inorganic constituents were not detected at concentrations above the corresponding MSC in groundwater samples that were filtered in the laboratory to evaluate dissolved concentrations of inorganics.

When reviewing the groundwater and soil analytical data together, the groundwater analytical results in Areas 1 and 2 indicate that residual soil impacts are not affecting the groundwater as follows:

- ***Area 1:*** *Eastern Part of Former Coal Storage Area*. SVOCs were not detected at concentrations greater than either the residential or non-residential MSCs in groundwater samples from any monitoring well in this area (MW-103, MW-108, MW-109, and MW-110).
- ***Area 2:*** *North/Northwest of Former Tar Storage Area*. SVOCs were not detected at concentrations greater than either the residential or non-residential MSCs in groundwater samples from any monitoring wells in this area (MW-101, PCMW-11S/D, PCMW-14S/D, and PCMW-17S/D) during the SRI.

Additionally, lead was not detected in any filtered groundwater samples at concentrations greater than the 5 µg/L MSCs indicating that lead concentrations in soil are not impacting groundwater.

The COCs in deep and shallow groundwater are identified in Table 3-7 below.

Table 3-7: Groundwater Constituents Exceeding Residential and Non-Residential MSCs

Analyte	CAS Number	Residential MSC Exceedance Frequency	Non-Residential MSC Exceedance Frequency

3.2.6 Soil Gas Quality

This section summarizes the quality of soil gas at the Site based on comparison of soil gas analytical results and existing soil and groundwater data to the screening values presented in the TGM.

3.2.6.1 Soil Gas Results

During the Initial RI activities, soil gas samples were collected from 21 locations to evaluate the potential for VI in future building development (see Figure 27). Due to the shallow water table, 20 of the 21 soil gas samples were collected from depths less than the desired depth of 5 feet bgs. The cover material at most of the soil gas sampling locations consisted of gravel or deteriorated asphalt pavement (not impervious surfaces). The soil gas sample data set is limited for use in VI evaluation in that only one round of soil gas data was collected (the TGM specifies two rounds) and the data were collected from shallower intervals than prescribed (i.e., intervals less than 5 feet below pervious surfaces can result in atmospheric air being introduced into the samples). Therefore, when paired with soil and groundwater data, the soil gas data are used herein as a semi-quantitative screening tool to aid in identifying areas that could potentially exhibit vapor intrusion concerns.

In response to the above circumstances, the soil gas analytical results were conservatively compared to residential and non-residential sub-slab soil gas SHS VI screening values (SV_{SS}) instead of near-source soil gas SHS VI screening values (SV_{NS}) for qualitative screening assessment purposes. The SV_{SS} screening values are much lower than the SV_{NS} screening values. As presented in Table 19, no VOCs were detected above the non-residential SV_{SS} in any of the soil gas samples. At sampling location PCSV-11, 1,4-dioxane was detected at a concentration of 440 micrograms per cubic meter (µg/m^3) which exceeds the 120 µg/m^3 residential SVss, but not the 3,100 µg/m^3 non-residential SVss. No other constituents exceed the residential SVss in any of the soil gas samples. More information on soil gas quality compared to residential standards is provided in Subsection 3.2.6.4.

3.2.6.2 Soil Analytical Results Compared to Vapor Intrusion Standards

The existing unsaturated soil analytical results were compared to the residential and non-residential VI standards from the TGM to evaluate the potential for VI concerns for future development. The soil analytical results compared to VI screening values are presented in Table 20.

From a total of 152 sampling locations where unsaturated soil samples were collected for laboratory analysis, soil analytical results exceed the non-residential VI screening values at 24 sampling locations and soil analytical results exceed the residential VI screening values at 26 sampling locations (two additional sampling locations compared to the non-residential standards). Benzene and naphthalene are the constituents that most frequently exceed the residential and non-residential VI screening values. Toluene, 1,1-biphenyl, and 2-methylnaphthalene also exceed the residential and non-residential VI screening values at select locations but were identified at the same locations where benzene and/or naphthalene exceedances were observed, with one minor exception. 1,1-Biphenyl was detected in the duplicate soil sample collected from PCTP-66R where no other constituents were detected above MSCs. Benzene, 1,1-biphenyl, 2-methylnaphthalene, and naphthalene were detected at concentrations an order of magnitude above the non-residential VI standards in soil. However, 1,1-biphenyl, 2-methylnaphthalene, and naphthalene concentrations in soil gas are limited by the soil saturation level (31.1 mg/kg, 1,000 mg/kg, and 73.2 mg/kg, respectively). Soil saturation levels are estimated based on site-specific information and chemical properties at an assumed soil/groundwater temperature of 62.6°F. Therefore, soil PAH concentrations have limited VI potential.

Dichloromethane exceeds the residential VI screening levels at three locations (but not the non-residential VI screening levels), and at two of these locations, dichloromethane was the only constituent

exceeding VI screening values. Most of the exceedances are within one of the four delineation areas (Areas 1 through 4), the Fuel Blending Area, or in the Site center near the Former Coke Operations Area. Soil sampling locations where constituents have been identified in vadose zone soil at concentrations greater than non-residential VI screening values are shown on Figure 28.

3.2.6.3 Groundwater Analytical Results Compared to Vapor Intrusion Standards

Groundwater samples collected from monitoring wells screened in the shallow groundwater zone were compared to applicable VI standards. At monitoring wells where groundwater was never observed to be within 5 feet of the ground surface, Arcadis compared the existing groundwater analytical results to the residential and non-residential VI standards. Per the TGM, Arcadis used the PADEP residential MSCs for used aquifers containing TDS ≤ 2,500 mg/L as the VI screening value for any wells where groundwater was at one point observed within 5 feet of the ground surface. Groundwater has been observed within 5 feet of the ground surface in 20 of 33 shallow monitoring wells. For the shallow groundwater zone, the groundwater analytical results compared to VI screening values are presented in Table 21.

Groundwater analytical results exceed the applicable non-residential VI screening values at 5 of 33 shallow monitoring wells (i.e., the same wells where groundwater was found to be impacted with constituents at concentrations exceeding MSCs for groundwater, as described in Subsection 3.2.5). Groundwater analytical results exceed the applicable residential VI screening values at 6 of 33 shallow monitoring wells (i.e., one additional monitoring well compared to the VI exceedance of the non-residential standard). Based on the SRI groundwater analytical results, potential VI concerns associated with groundwater appear to be limited to only three monitoring well locations (MW-5, MW-107, and MW-111). VOC and SVOC concentrations in groundwater samples collected from MW-5 and MW-107 are generally consistent with or only slightly greater than VI screening values in groundwater samples collected from MW-5 and MW-107. Based on the groundwater analytical results for wells located downgradient of MW-111 (i.e., MW-112 and MW-113), potential vapor concerns from groundwater impacts are isolated to the immediately vicinity of MW-111 (Area 4). Groundwater monitoring wells where constituents have been identified at concentrations greater than VI screening values are shown on Figure 29.

3.2.6.4 Offsite Soil Vapor Evaluation

To evaluate the potential for VI concerns off-site, the soil-gas, soil, and groundwater analytical data were compared to the applicable residential VI screening values, as introduced in the previous subsections. Based on available data, there are no potential VI concerns for the residential properties adjacent to the Site.

When comparing the analytical data to residential VI standards, one soil-gas sampling location, two additional soil sampling locations, and one additional groundwater monitoring well are added to areas of potential VI concern that had been identified based on comparison to non-residential VI standards. Where applicable residential VI screening values are exceeded, proximity distances were used to evaluate the potential for VI concerns offsite in accordance with the TGM. Proximity distances of 30 feet for petroleum constituents and 100 feet for non-petroleum constituents are specified in the TGM.

Most sampling locations or monitoring wells where constituents were identified at concentrations exceeding applicable VI standards are near the center of the Site and would not affect offsite properties.

However, 100-foot proximity distances around sampling locations PCTP-66 and S-156 extend offsite for non-petroleum constituents, but the proximity distances do not extend below offsite buildings. These locations are not adjacent to, or across the street from, residential properties. Sampling location PCTP-66 is across the street from a commercial/industrial property where clothing is sold and printed with custom prints. Sampling location S-156 is across the street from a car impoundment lot that appears to be loose gravel. The proximity distances for sampling locations and monitoring wells where constituents exceed the residential VI screening values are shown on Figure 30. In conclusion, there are no potential VI concerns offsite from conditions onsite.

3.2.6.5 Soil Vapor Constituents of Concern

When compared to applicable non-residential VI standards, soil and groundwater analytical results indicate the potential for soil VI in future buildings in certain limited areas onsite in the absence of remediation or mitigation. Benzene is the constituent most frequently detected above non-residential VI standards in both soil and groundwater samples. PAHs also frequently exceed the non-residential VI standards in soil but are limited by the soil saturation levels. Therefore, PAHs in soil have limited VI potential. However, soil gas sampling results did not exceed any of the sub-slab VI screening values indicating that the VI potential is likely over predicted by the soil and groundwater analytical results. The COCs potentially causing VI concerns are identified in Table 3-8 below.

Table 3-8: Groundwater Constituents Exceeding Residential and Non-Residential VI Screening Values

Analyte	CAS Number	VI Screening Values for Soil Exceedance Frequency	VI Screening Values for GW Exceedance Frequency
Volatile Organic Compounds			
Benzene	71-43-2	20/175	5/103
Methyl-tert-butyl ether	1634-04-4	0/53	1/36
Toluene	108-88-3	3/177	0/103
Trichloroethene	79-01-6	0/136	1/103
Semi-Volatile Organic Compounds			
1,1-Biphenyl	92-52-4	3/54	0/36
2-Methylnaphthalene	91-57-6	1/179	0/103
Naphthalene	91-20-3	19/179	0/103

Note: GW = groundwater.

4 GROUNDWATER MODELS

Fate and transport and mass flux modeling was conducted upon completion of the groundwater sampling to assess the groundwater conditions at the Site and at the property boundaries. The objective is to develop groundwater models for the Site that can be used as a basis for predicting the current and potential future extent of groundwater concentrations for select VOCs and SVOCs at Site boundaries above MSCs. Results of the models are used to estimate the movement of the constituents over time and assess the potential for impacts due to constituent mass migration and discharge to the Delaware River.

The fate and transport model evaluates the constituent concentrations in shallow groundwater at the property boundaries. The mass flux calculation evaluates the mixing concentration of PAHs from deep groundwater onsite to the Delaware River using data from PCMW-09D.

A summary of the hydrogeological setting and relevant surface water comparison values is below followed by the fate and transport model. The mass flux calculations are presented in Section 4.4.

4.1 Hydrogeologic Setting

As discussed in Section 3.2.2, three hydrostratigraphic units exist at the Site: the fill, silt and clay, and sand and gravel, and groundwater at the Site is separated into a shallow and deep zone by the silt and clay layer.

4.1.1 Shallow and Deep Groundwater Zones

The shallow groundwater is encountered in the urban/historic fill unit across the Site at depths of approximately 2- to 12- feet bgs. Based on regional groundwater information, this shallow groundwater zone is a perched aquifer that was created by the placement of fill over the native silt and clay layer. As shown on Figures 8, 9, and 10, groundwater in the fill is mounded in the central/southern portion of the Site and flows radially outward from the mound. The hydraulic conductivity of the fill ranges from approximately $1.47x10^{-4}$ to $2.93x10^{-3}$ centimeters per second (cm/sec)[16].

The deep aquifer zone is observed at approximately 9- to 17-feet bgs in the sand and gravel unit. On average the sand and gravel unit was encountered at 20.25 feet bgs. As indicated by Figures 11 and 12, groundwater in the sand and gravel flows eastward, toward the Delaware River. The sand and gravel is the most permeable hydrostratigraphic unit beneath the Site and has a hydraulic conductivity of $2.73x10^{-3}$ to $1.79x10^{-1}$ cm/sec.

4.1.2 Hydraulic and Hydrologic Boundaries

The Site is in the Lower Delaware River Watershed and borders the Delaware River to the southeast. Frankfort Creek and the Tookany/Tacony-Frankford watershed is approximately 2,000 feet southwest of the Site (from Site boundary). The Bridesburg Channel (which aerials indicate was the historical course of Frankford Creek), is north of the Site. Both Frankford Creek and the Bridesburg Channel drain to the Delaware River. The shallow groundwater, which mounds in the center of the Site and flows radially

[16] Hydraulic conductivity values were calculated based on slug test data reported by WCC (WCC 1986) and laboratory soil testing results reported by PSS.

outward, is expected to drain to the Delaware River via Frankford Creek, Bridesburg Channel, or other local drainage features between the Site and these water bodies. Deep groundwater at the Site flows directly to the Delaware River.

As indicated in Subsection 3.2.2.1, a groundwater use survey was conducted in the vicinity of the Site to confirm that no known or suspected users of groundwater exist in the regulatory-required survey area. A total of 65 wells were located within a ½-mile radius of the Site. All the wells surrounding the Site are, or are suspected to be, unused, abandoned, or only used for environmental investigations and clean-ups. A total of 4 wells surrounding the Site are listed as withdrawal wells. The withdrawal wells appear to be related to the environmental investigation and cleanup efforts at the former Rohm and Haas Chemical Company Facility (Pennsylvania Facility ID 742771 and NIR number 61614). This facility is approximately 1/3 mile north of the Site.

4.2 Relevant Surface Water Comparison Values

At the point-of-compliance wells closest to the Delaware River (MW-107 for shallow groundwater and PCMW-09D for deep groundwater), the SVOCs that exceed groundwater MSCs were also compared to the following surface water criteria:

1. Delaware River Basin Commission (DRBC) Surface Water Criteria (recorded from Tables 3 through 7 of the Administrative Manual - Part III Water Quality Regulations with Amendments through December 4, 2013: 18 CFR Part 410 for the DRBC).
2. PADEP Surface Water Criteria for Fish and Aquatic life from 25 Pa. Code § 93.8c Table 5.
3. PADEP Surface Water Criteria for Human Health from 25 Pa. Code § 93.8c Table 5.

Although 25 PA Code § 93.9e defines the portion of the Delaware River adjacent to the Site (Tidal Portions from River-Mile 108.3 to Big Timber Creek) for warm water fish (maintenance only) and migratory fish (passage only), the human health criteria were used as the edge criterion when modeling to be conservative. This portion of the Delaware River is also DRBC Water Quality Zone 3.

4.3 Fate and Transport Model

The purpose of the groundwater fate and transport modeling was to evaluate: (1) the extent of constituent migration in groundwater in the absence of any remedial activities (i.e., baseline conditions); and (2) the potential to either achieve equilibrium/stabilization or a reduction of constituent concentrations. Model development, analysis, and documentation were performed in accordance with the guidelines provided in Pennsylvania's Land Recycling Program Technical Guidance Manual. Results of the fate and transport simulations are used to estimate the movement of the constituents over time, and to assess the potential for impacts due to constituent mass migration and discharge to adjacent surface waters.

This section documents the fate and transport modeling effort, provides an evaluation of model applicability, and reports the results of the fate and transport simulations.

4.3.1 Constituents and Monitoring Wells Selected for Modeling

As discussed in Section 3.2.5, groundwater quality at the Site is relatively unimpacted by former Site operations and source material is not present onsite. Only the SRI groundwater data was considered for

fate and transport analysis because the Initial RI data is more than 12 years old, and the SRI groundwater data indicates that VOCs and SVOCs were detected at much lower concentrations during the SRI then the Initial RI at the same wells (or installed replacement wells). Additionally, fate and transport analysis was only performed on groundwater impacts identified in point-of-compliance monitoring wells, defined herein as the most downgradient well in that area of the Site.

During the SRI, select VOCs and SVOCs were identified in groundwater samples from three point-of-compliance monitoring wells at concentrations exceeding applicable MSCs (MW-5, MW-102, and MW-107). The point-of-compliance monitoring wells are screened in the fill layer and sample the shallow groundwater zone. The constituents that exceed MSCs and were considered for Fate and Transport analysis at these monitoring wells are listed on Table 4-1 below:

Table 4-1: Groundwater Constituents Considered for Modeling

Monitoring Well	Date	Constituent	Concentration (µg/L)	MSC (µg/L)	Modelled (Y/N)
MW-5	3/19/18	Trichloroethene	6.1	5	Y
MW-102	5/31/18	Bis(2-ethylhexyl)phthalate	<2.4 [11.3]	6	Y
MW-107	5/30/18	Methyl-tert-butyl ether	20.7	20	N
MW-107	5/30/18	Benzo(a)pyrene	1.2	0.2	Y
MW-107	5/30/18	Benzo(b)fluoranthene	1.7	1.2	Y
MW-107	5/30/18	Benzo(g,h,i)perylene	0.95	0.26	N

Notes: MSCs are the soil-to-groundwater MSCs for a non-residential used aquifer with TDS less than or equal to 2,500 ppm. Bis(2-ethylhexyl)phthalate) was not detected above the 2.4 µg/L laboratory detection limit in the parent sample from MW-102, but the constituent was detected at 11.3 µg/L in the duplicate sample collected from the same location.

TCE, bis(2-ethylhexyl)phthalate, BaP, and BbF were selected for modeling. Methyl-tert-butyl ether and benzo(g,h,i)perylene were not modeled because surface water criteria has not been established for these constituents. BaP and BbF concentrations at MW-107 exceed the surface water criteria as indicated in Table 4-2 below:

Table 4-2: MW-107 Groundwater Constituents Exceeding MSCs Surface Water Criteria

Constituent	PADEP Human Health Surface Water Criteria	DRBC Water Quality Criteria		MW-107
		Marine Objective - Fish Ingestion Only	Max	5/30/18
Methyl-tert-butyl ether	- -	- -	- -	20.7
Benzo(a)pyrene	0.0001	0.018	0.2	**1.2**
Benzo(b)fluoranthene	0.001	0.18	- -	**1.7**
Benzo(g,h,i)perylene	- -	- -	- -	0.95 J

Notes: The bolded values indicate that the constituent's concentration at MW-107 exceeds the criteria. All concentrations reported in µg/L. "- -" indicates constituent not listed in guidance document.

4.3.2 Analytical Models

Domenico analysis was used to model the groundwater impacts for the constituents listed in Table 4-1 (Domenico 1987). The Domenico Model was chosen as per Pennsylvania's Land Recycling Program Technical Guidance Manual because there is little variation in conditions over the model domain, with a simple plume geometry and conceptual model. The spreadsheets used were downloaded from the PADEP website following link: https://www.dep.pa.gov/Business/Land/LandRecycling/Standards-Guidance-Procedures/Guidance-Technical-Tools/Pages/Fate-and-Transport-Analysis-Tool.aspx

Both spreadsheets are based on the following equation:

$$C(x,y,z,t) = \left(\frac{C_o}{8}\right)\exp\left\{\frac{x}{2\alpha_x}\left[1-\left(1+\frac{4\lambda\alpha_x}{v}\right)^{\frac{1}{2}}\right]\right\} erfc\left\{\left[x - vt\left(\sqrt{1+\frac{4\lambda\alpha_x}{v}}\right)\right]/2\sqrt{\alpha_x vt}\right\}$$
$$\left\{erf\left[(y+Y/2)/2\sqrt{\alpha_y x}\right] - erf\left[(y-Y/2)/2\sqrt{\alpha_y x}\right]\right\}\left\{erf\left[(z+Z/2)2\sqrt{\alpha_z x}\right] - erf\left[(z-Z/2)/2\sqrt{\alpha_z x}\right]\right\}$$

where:

C(x,y,z,t) = the concentration of the constituent at location x, y, z from the source at time t.

C_o = source concentration – the highest concentration of the constituent in the groundwater at the source (derived from site-specific data).

α_x = longitudinal dispersivity (well- / location- specific data).

α_y = transverse dispersivity (well- / location- specific data).

α_z = vertical dispersivity (default value of 0.001 foot).

K = hydraulic conductivity (calibrated data).

i = hydraulic gradient (well- / location- specific data).

f_{oc} = fraction of organic carbon expressed as a decimal (default value of 0.005).

p_b = bulk density (laboratory soil testing results).

n_e = effective porosity (calibrated data).

K_{OC} = the organic carbon partition coefficient (default value from Table 5 in PA Code Title 25, Chapter 250).

R = retardation factory (calculated as $1+((K_{OC}*f_{oc}*p_b)/n_e)$).

v = constituent velocity (calculated as v_s/R).

v_s = seepage velocity (calculated as $v_s = Ki/n_e$).

λ = first order decay constant (default value from Table 5 in PA Code Title 25, Chapter 250).

Y = width of source area (well- / location- specific data).

Z = depth of source area (well- / location- specific data).

x,y,z = spatial coordinates in the horizontal, transverse and vertical directions.

t = time since the plume started moving.

Groundwater impacts originating from MW-5 and MW-102 were modeled using PADEP's Quick Domenico (QD) spreadsheet to evaluate groundwater concentrations of the selected constituents at the property boundary. Groundwater impacts originating from MW-107 were modeled using PADEP's SWLoad5B spreadsheet to estimate the mass loading of the selected constituents from groundwater to the Delaware River.

The results were loosely calibrated to available data from the MW-111 to MW-112 monitoring well pair.

4.3.2.1 Quick-Domenico Model

The QD application spreadsheet calculates the concentration anywhere in a plume of impacts at any time after a continuous, source becomes active. The QD model is intended for dissolved organic constituents whose fate and transport can be described or influenced by first order decay and reaction with organic carbon in the soil. The model assumes a constant source of a user-defined width which contributes impacts to the groundwater system, which has a defined constant flow velocity and direction, dispersion, linear isotherm adsorption (retardation), and first-order decay. All parameters are assumed constant in space and time. The QD mode also calculates the concentrations in a two-dimensional 5x10 grid whose length and width are set by the user.

Quick-Domenico Model Limitations

The major limitation of the QD model is that steady, uniform, one dimensional groundwater flow is assumed. The QD model is limited so that it should not be utilized for sites where flow and transport parameters vary significantly in direction or magnitude over the model domain. The QD model is intended for use in unconsolidated aquifers with reasonably uniform physical and hydrogeologic properties. The QD model does not simulate the transformation of parent compounds into daughter compounds, nor does it consider reactions between compounds. The mounding groundwater flow at this Site is simplified by isolating constituent concentrations (as supported by available groundwater data) to portions of the water table where flow is uniform and one dimensional.

4.3.2.2 SWLoad

The SWLoad spreadsheet uses a rearrangement of the Domenico equation to calculate concentrations at different points in the cross section of a plume at a distance from a continuous finite source. The concentrations are then added and multiplied by the groundwater flux and can be used to estimate the mass loading of a particular constituent from diffuse groundwater flow to a stream or surface water body. SWLoad assumes that the calculated loading is discharged to the subject stream.

SWLoad is intended to provide an estimate of the mass loading and is intended as screening tool. Therefore, if the mass loading is within the neighborhood of 30-50% of the level that would violate a stream standard, more rigorous in-stream sampling, monitoring and modelling efforts should be considered.

SWLoad Model Limitations

SWLoad has the same limitations as the QD model and is primarily intended for use in unconsolidated (soil) aquifers with reasonably uniform physical and hydrogeologic properties.

4.3.3 Groundwater Flow Model Construction and Parameters

As indicated in Section 4.3.2 model parameters were selected based on a combination of literature values, site-specific data, and calibration. Parameters obtained using the QD model were also used for SWLoad.

4.3.3.1 Literature Values

The chemical specific values (i.e., first order decay constant [λ] and the organic carbon partition coefficient [K_{OC}]) were those provided in Table 5a of PA Code Title 25, Chapter 250. Additionally, the default value of 0.5% organic carbon was used.

4.3.3.2 Laboratory Soil Testing Results

Site-specific parameters were estimated via laboratory soil testing performed on soil samples collected from the borings drilled to install monitoring wells PCMW-14D and PCMW-16D. Laboratory soil samples were collected from each hydrostratigraphic unit. Soil samples were not collected from the monitoring wells selected for modelling (MW-5, MW-102, or MW-107). Therefore, physical parameters of soil samples collected from monitoring wells PCMW-14D and PCMW-16D were used as starting points for calibrating the model. Parameters relevant to modelling provided by laboratory soil testing are hydraulic conductivity, porosity, and soil bulk density. For the fill unit, laboratory soil tests provided the following value range for each of these parameters:

- Hydraulic Conductivity (K): 0.417 to 8.31 feet per day (ft/day: $1.47x10^{-4}$ to $2.93x10^{-3}$ cm/sec).
- Porosity (n_e): 0.519 to 0.529.
- Density (p_b): 1.19 to 1.29 grams per cubic centimeter (g/cm^3).

The results of the laboratory soil testing are included in Appendix F. As a note, hydraulic conductivity, porosity, and bulk density are used to calculate constituent velocity used in the Domenico equation. Therefore, infinite combinations of these parameters could result in the same velocity and, thus, the same results.

4.3.3.3 Well- / Location- Specific Data

Many of the parameters in the Domenico equation are based on well location or the site-specific conditions in the vicinity of that well. These parameters include the hydraulic gradient, dispersivity, and source dimensions. As noted on the QD information sheet, longitudinal dispersivity (αx) is derived by dividing the distance from the source to the point of concern (property boundary) by 10 and the transverse dispersivity (αy) is calculated by dividing longitudinal dispersivity by 10. Vertical dispersivity selected was 0.001 feet, as suggested as a conservative value in the SWLoad Instructions. Source dimensions were roughly selected based on soil data. The hydraulic gradients used in the QD model were estimated using the groundwater contour maps (Figures 8 through 10) and averaging the approximate hydraulic gradient for each event. Well- and location- specific physical parameters selected for modelling are provided in Table 4-3 below.

Table 4-3: Well- / Location- Specific Parameters

Monitoring Well	Hydraulic Gradient (ft/ft)	Dispersivity (feet)		Source Width (feet)	Source Depth (feet)
		ax	ay		
Calibration Pair					
MW-111 to MW-112	0.0101	20.4	2.4	200	10
Modeled Wells					
MW-5	0.00855	13.8	1.38	200	10
MW-102	0.00506	30	3	200	10
MW-107	0.00294	7	0.7	160	10

4.3.3.4 Calibration

During the SRI, monitoring wells cluster MW-108 through MW-110 and cluster MW-111 through MW-113 were installed to investigate groundwater concentrations at and downgradient from potential source areas. Downgradient wells, MW-109, MW-110, MW-112, and MW-113, indicate that groundwater is not migrating offsite from the source areas at concentrations exceeding MSCs. Furthermore, most VOC and PAH constituents were not detected in groundwater at these downgradient monitoring wells above laboratory detection limits.

Benzene in well cluster MW-111 through MW-113 was selected for calibration. This well cluster is approximately 1,260 feet from MW-5, 1,240 feet from MW-102, and 600 feet from MW-107. Groundwater direction at the calibration well cluster is most similar to the groundwater direction at MW-102.

Benzene was detected in groundwater from MW-111 at a concentration of 686 µg/L, and benzene was not detected above the 0.5 µg/L laboratory detection limit in groundwater from the downgradient wells (i.e., MW-112, MW-113). For calibration purposes, a benzene concentration half the laboratory detection limit (0.25 µg/L) was modeled at downgradient wells.

For calibration, a time of 37 years was used because the groundwater data was collected in 2019 which is approximately 37 years since Site closure in 1982. The lowest laboratory values for porosity (0.519) and bulk soil density (1.19 g/cm^3) were used as a conservative measure to provide the fastest constituent velocity. A 0.005 organic carbon fraction was used as recommended in the SWLoad Construction Manual (PADEP 2008). Additionally, the October 3, 2019 shallow groundwater potentiometric surface is different than the previous shallow groundwater potentiometric surfaces in this immediate area. Therefore, the model was calibrated twice: first using the March 19, 2018 shallow groundwater flow direction; and second using the October 3, 2019 shallow groundwater flow direction. Benzene isoconcentration maps modelled based on both flow directions are shown on Figures 31 and 32.

Hydraulic conductivity was the only parameter further calibrated. The hydraulic conductivity for the March 19, 2018 groundwater model was 1.185 ft/day, and the hydraulic conductivity for the October 3, 2019 groundwater model was 1.317 ft/day. Both calibrated values for hydraulic conductivity fall within the 0.417 to 8.31 ft/day range established by laboratory soil testing. The 1.317 ft/day hydraulic conductivity was used for modelling at MW-5, MW-102, and MW-107.

4.3.4 Predictive Simulations

The QD model was adjusted to determine concentrations at the point of compliance (property line) in 5, 10, 15 and 30-year durations. The SWLoad model assumes a near infinite time (when concentrations at boundary locations would be the highest for a constant source). Copies of the results of the QD and SWLoad models are included as Appendix L. For some models, please note that the constituent concentration was inputted as µg/L opposed to the default mg/L to provide a cleaner presentation of the results (i.e., to limit the use of scientific notation for results much less than 0). Unit changes are noted in PDF edits for the model. The modeling results are presented below:

- *TCE at MW-5* – The 30-year (highest) modeled concentration for TCE is 1 µg/L at the Site boundary. Modelling indicates that the constituent would not leave the Site in groundwater at concentrations greater than the 5 µg/L MSC.
- *Bis(2-ethylhexyl)phthalate at MW-102* – The modeled concentration for bis(2-ethylhexyl)phthalate is 0 µg/L at the Site boundary for each of the timeframes modelled. Modelling indicates that the constituent would not leave the Site in groundwater.
- *Benzo(a)pyrene and benzo(b)fluoranthene at MW-107* – The modeled concentrations for both these constituents indicate that groundwater conditions at the Site boundary would not exceed surface water criteria. The estimated concentrations are many orders of magnitude less than the conservative PADEP Surface Water Criteria for Human Health. At the Site boundary, the predicted concentrations for both these constituents are rounded to zero in the model causing a #DIV/0! error in the spreadsheet when outputting the mass loading estimate.

When combined with the groundwater data at point-of-compliance wells, fate and transport modeling results indicate that COCs are not currently, and are not predicted in the future, to migrate offsite in groundwater.

4.4 Mass Flux Evaluation

This section presents mass flux calculations for BaA, BaP, BbF, and chrysene from the deep groundwater zone around monitoring well PCMW-09D to the Delaware River. As discussed in Subsection 3.2.5.3, these four constituents were identified at concentrations exceeding the residential and/or non-residential groundwater MSCs in the January 31, 2006 groundwater sample collected from monitoring well PCMW-09D.

The mass flux evaluation presented herein uses the January 31, 2006 groundwater data from monitoring well PCMW-09D, Initial RI laboratory soil testing data, Site-specific geologic/hydrogeologic, and streamflow data from the United States Geologic Survey (USGS). The calculations in this evaluation are considered conservative for several reasons as detailed in the discussion that follows.

The most conservative assumption is that the January 31, 2006 groundwater analytical data from PCMW-09D are representative of the PAH concentrations throughout the deep aquifer at the interface with the Delaware River. These PAHs generally adsorb to organic carbon in soil and are mostly immobile in groundwater. As described in Subsection 3.2.5.3, this is the only monitoring well where PAHs have been detected in deep groundwater at concentrations exceeding the MSCs. These PAHs were not detected above laboratory detection limits in the November 17, 2005 groundwater sample collected from PCMW-

09D. Therefore, the PAH concentrations detected in the January 31, 2006 groundwater sample from PCMW-09D are likely attributed to sample turbidity and biased high. Considering the information above, this assumption represents a worse-case scenario for PAH mass loading into the Delaware River.

4.4.1 Calculation of Groundwater Flow

The first step to calculating mass flux of dissolved phase constituents in the deep aquifer to the Delaware River is to estimate the approximate groundwater flow into the river from the sand and gravel unit using the following equation:

Groundwater flow, QGW, from the Site to the river was calculated using revised Darcy's Law:

$$Q_{GW} = L * B * K * i$$

where:

L = length (perpendicular to groundwater flow) of the sand and gravel unit along the river that is assumed to discharge to the river (length).

B = average saturated thickness of the sand and gravel unit assumed to discharge to the river (length).

K = hydraulic conductivity of the sand and gravel unit (length/time).

I = average horizontal gradient of groundwater in the sand and gravel unit (length/length).

The cross-sectional length selected for this calculation was based on groundwater flow patterns and observed geology at the Site. Groundwater flow patterns in the sand and gravel unit are predominately toward the Delaware River, and it is assumed that all the groundwater flow in the unit discharges into the river. The sand and gravel unit is continuous across the Site. Therefore, the maximum width of the Site of approximately 1,500 feet (the approximate distance tracing the utility corridor from Buckius Street to Orthodox Street) was used for the length of the cross-sectional flow.

The sand and gravel unit at the Site is a confined aquifer. The average distance between the top of the underlying bedrock and the bottom of the overlying organic silt and clay units were used to calculate the average saturated thickness of the sand and gravel unit. The average depth to the top bedrock and to the bottom of the silt and clay unit are 77.50 feet and 30.25 feet bgs respectively[17]. Therefore, the average saturated thickness of the sand and gravel unit is 47.25 feet. Based on the average saturated thickness and the length of the cross-sectional flow, a cross-sectional area of 70,875 square feet was used for these calculations.

Hydraulic conductivity values (K) were calculated for the sand and gravel unit during the Initial RI by sieve (grain) size analysis. The geometric mean K-value from the two sieve size analyses from borings adjacent to PCMW-09D (borings PCMW-10D and PCMW-14D) were used for the groundwater flow calculations. The K value used for the groundwater flow equation was 318 feet/day.

Groundwater elevations measured in wells screened across the sand and gravel unit between October 2005 and March 2006 were used to calculate the hydraulic gradient of the deep unit. The average

[17] Observations at PCSB-13 were not used for the mass flux calculation. The deeper bedrock and thicker sand and gravel unit observed at the other wells assumes a larger cross-sectional area of the deep aquifer which biases high the Site's influence on the Delaware River. This a conservative assumption.

groundwater elevation across the five measurement events were used for each well. The gradients (difference in head between two wells divided by the distance between the wells) between PCMW-09D and eight upgradient wells were calculated. The 0.00043 feet/feet average hydraulic gradient of the deep aquifer was used for these calculations.

Using the above-described variables, the groundwater flow rate through the sand and gravel unit to the Delaware River is 9,691 cubic feet/day or 50.3 gallons/minute. Table 4-4 lists each variable and input value used to calculate groundwater flow.

Table 4-4: Site-Specific Parameters

Input Parameters	Input Values
Aquifer Length (ft)	1,500
Aquifer Thickness (ft)	47.25
Aquifer Cross Sectional Area (ft^2)	70,875
Geometric Mean Hydraulic Conductivity (ft/day)	318
Horizontal Hydraulic Gradient (ft/ft)	0.00043
Groundwater Flow to The River (ft^3/Day)	9,691
Groundwater Flow to The River (gallons/minute)	50.3

4.4.2 Mass Flux from Site to Delaware River

The maximum historical PAH concentrations at PCMW-09D were used to calculate mass fluxes for each of the three PAHs. Mass flux was calculated using the following equation:

$$M = Q_{GW} * C_{GW}$$

where:

Q_{GW} = groundwater flow from the Site into the Delaware River (calculated above) (volume/time).

C_{GW} = maximum groundwater PAH concentration in PCMW-09D.

The PAH groundwater concentrations from PCMW-09D and calculated mass fluxes are presented in Table 4-5 below.

Table 4-5: PAH Mass Flux

Constituent	PCMW-09D 1/31/06 (µg/L)	Mass Flux (pounds/day)
Benz(a)anthracene	2.0	0.0012
Benzo(a)pyrene	1.7	0.0010
Benzo(b)fluoranthene	2.5	0.0015
Chrysene	2.0	0.0012

4.4.3 Mixing Concentration

The following equation was used to calculate the mixing concentration, C_{Riv} (mass/volume):

$$C_{Riv} = M / (Q_{GW} + Q_{Riv})$$

where:

M = the mass flux of each constituent (mass/time)

$\boldsymbol{Q_{GW}}$ = the groundwater flow rate to the river through the sand and gravel unit along the cross-sectional area (volume/time)

$\boldsymbol{Q_{Riv}}$ = the river flow rate adjacent to the Site (volume/time)

As a conservative measure, the 7Q10 flow for the river was used for Q_{Riv}. The 7Q10 is the lowest 7-day average flow that occurs (on average) once every 10 years. The USGS software SWToolbox was used to calculate the 7Q10 based on the USGS gauging data recorded from February 1, 1913 through February 8, 2022 at the Delaware River gauging station in Trenton, New Jersey. The software calculated the 7Q10 at the Trenton, New Jersey location at 1,771 cubic feet per second (cfs). Per the procedure described in the EPA Low Flow Statistics Tools Handbook (EPA, 2018), Arcadis calculated the 7Q10 flow (volume/time) of the section of the Delaware River adjacent to the Site using the following equation:

$$7Q10_{Riv} = 7Q10_{Gauge} * \frac{A_{Riv}}{A_{Gauge}}$$

where:

$\boldsymbol{7Q10_{Riv}}$ = the 7Q10 discharge of the river adjacent to the Site (volume/time)

$\boldsymbol{7Q10_{Gauge}}$ = the 7Q10 discharge of the river adjacent to the Site (volume/time)

$\boldsymbol{A_{Riv}}$ = Drainage area of the river adjacent to the Site (area)

$\boldsymbol{A_{Gauge}}$ = Drainage area of the river at the gauging station (area)

Based on drainage areas of 7,920 and 6,780 miles^2 for the area adjacent to the Site and the gauging station respectively, the 7Q10 value of the section of the river adjacent to the Site is 2,068 cfs.

The calculated mixing concentrations are presented in Table 4-6 along with comparisons to the surface water criteria presented in Section 4.2.

Table 4-5: Delaware River Mixing Calculations

Constituent	PADEP Human Health Surface Water Criteria	DRBC Water Quality Criteria		Delaware River Mixing Concentration
		Marine Objective - Fish Ingestion Only	Max	
Benz(a)anthracene	0.001	0.18	- -	0.00011
Benzo(a)pyrene	0.0001	0.018	0.2	0.000092
Benzo(b)fluoranthene	0.001	0.18	- -	0.0014
Chrysene	0.12	18	- -	0.00011

Notes: All concentrations reported in µg/L. "- -" indicates constituent not listed in guidance document.

4.4.4 Conclusion

Mixing concentrations of BaA, BaP, BbF, and chrysene were calculated using groundwater flow data, mass fluxes, and 7Q10 flow of the Delaware River. The calculations were based on onsite and offsite groundwater sampling data. Based on calculations and comparisons presented in Table 4-5, actual mixing concentrations for the selected PAHs are below the applicable and conservative surface water standard values. Therefore, PCC proposes to prepare an Act 2 Final Report for groundwater upon approval of this RI Report and Cleanup Plan.

5 CONCEPTUAL SITE MODEL

This section presents the CSM which has been prepared in accordance with the PA Code Title 25, Chapter 250.404 and follows EPA (1989) guidance. The CSM outlines potential source areas, release and transport mechanisms, environmental media that currently show or may show the presence of COCs in the future, possible exposure pathways to potentially exposed human populations, and potential exposure routes. It considers current Site conditions and surrounding land use, as well as the most likely future conditions upon redevelopment for future commercial or industrial land use.

The primary exposure source is onsite soil that contains COCs common in urban/historic fill and/or residual COCs from former Site-related activities. Figure 33 contains a graphic illustration of the CSM for the Site. As shown in the figure, the primary exposure source is onsite soil. Table 22 includes information on pathway elimination for both current and future Site receptors.

A complete exposure pathway is composed of the following four elements (EPA 1989):

- A source and mechanism of COC release.
- Retention or transport media.
- A potential contact point with an affected medium.
- An exposure route (i.e., ingestion, dermal contact, inhalation) at the potential contact point.

If any of the elements are or will be missing, the exposure pathway is incomplete, and there is no potential for exposure or health risk. This is the premise behind “pathway elimination” cleanup strategy. Exposure pathways are depicted as potentially complete where it has not been confirmed that any of the elements of an exposure pathway are missing.

5.1 Current Exposure Pathways

The Site is currently vacant; therefore, based on the current use of the Site there are no potential human receptor populations that may contact COCs onsite. In the event that the Site is redeveloped, and buildings are constructed, there are potentially complete future VI pathways.

5.1.1 Current Soil Pathways

The Site is currently vacant and access to the impacted areas of soil onsite is currently restricted by a chain-link fence that encloses the entire Site. In addition, most of the Site is either densely vegetated (woodlands and mowed grass) or covered by impervious surfaces such as pavement or remaining building structures or features such as concrete pads or footings, which limit the ability of surface soils to be eroded or mobilized and encountered by human receptors.

Outdoor maintenance workers mow herbaceous vegetation at the Site a few times a year and mow to a grass height of 6 inches or higher. Subsurface utility work is not anticipated because subsurface utilities were disconnected as part of Site demolition activities, except for the Upper Delaware Collecting Sewer which extends beneath the Site and can be accessed from a manhole near the western end of the Site. Additionally, any Site workers must follow the HASP and use personal protective equipment (PPE) that will mitigate soil exposure pathways. Site worker (both outdoor worker and utility worker) exposure to soils

are eliminated by the presence of vegetation and impervious surfaces, as well as the adherence of safe work practices as prescribed in the HASP. Therefore, there are no potential receptors for onsite soil dermal contact or ingestion and this pathway is incomplete.

5.1.2 Current Groundwater Pathways

Drinking water in Philadelphia is solely sourced from the Delaware and Schuylkill Rivers. Groundwater is not used for drinking water in Philadelphia. As shown in Figure 13 and presented in Appendix J, there are no active groundwater wells at the Site or in the immediate Site area. Therefore, the current exposure pathway for groundwater as potable water or industrial water is incomplete. In the future, as part of the Site redevelopment, institutional controls will be established that prohibit groundwater use.

There are no groundwater seeps at the Site, so there is no pathway to groundwater exposure unless intrusive work is performed below the water table. There is only one active manhole which provides access to the Upper Delaware Collecting Sewer. All other utilities were disconnected during previous Site demolition/decommissioning activities. The Upper Delaware Collecting Sewer does not collect any storm water from the Site. No installation, maintenance, or repair of underground utilities is anticipated under current conditions.

5.1.3 Current Vapor Intrusion Pathways

There are no buildings currently onsite; therefore, the current VI pathways via onsite groundwater and soil are incomplete.

5.2 Future Exposure Pathways

The following hypothetical potential human receptor populations were identified and the potential for their exposure was evaluated under the future exposure scenario:

- Construction workers
- Utility workers who may install or maintain utilities on the Site
- Outdoor workers
- Building occupants and indoor workers
- Residents, if Site use is not restricted
- Recreational users
- Trespassers

Biota may be exposed to COCs in surface soil (top 2 feet) via direct contact, ingestion, inhalation, and food-web transfer. Potential risks from inhalation or dermal exposures are typically not quantified for wildlife because of the lack of acceptable methodology to quantify exposure.

5.2.1 Future Soil Pathways

Future exposure pathways via direct contact with soils for incidental ingestion, dermal contact and/or inhalation of fugitive dusts or COCs volatilized from soils would be complete in scenarios where the

Cleanup Plan is not implemented. Future soil exposure pathways would include the following individuals who may encounter COCs in surface and subsurface soil via incidental ingestion, dermal contact, and the inhalation of VOCs and/or particulates in windblown soil:

- Residents.
- Recreational users.
- Building occupants and indoor workers.
- Construction and utility workers.
- Outdoor workers (such as lawn maintenance personnel).
- Trespassers.

5.2.2 Future Groundwater Exposure Pathways

The depth to groundwater ranges from approximately 2 to 15 feet bgs across the Site, except at one isolated location, PCMW-12S, where groundwater (likely perched) was observed at a depth of 0.78 feet bgs. Therefore, similar to future soil exposure pathways, future exposure pathways via direct contact with groundwater for incidental ingestion, dermal contact, and/or inhalation of COCs volatilized from groundwater may potentially exist for future residents, construction workers, and utility workers. There is a complete exposure pathway for utility workers and residents who may be exposed to COCs in shallow groundwater, via dermal contact and inhalation of VOCs while performing utilities installation or maintenance on the Site or using groundwater (without restrictions or treatment) for drinking water. Volatile constituents in groundwater may volatilize into utility trenches. Construction workers are potential candidates for exposure to COCs in groundwater, if excavation dewatering is performed during Site redevelopment. If fill material were to be placed in areas of the Site with a shallow groundwater table prior to building construction, this may limit excavation below the water table (e.g., for installation of utilities).

As previously discussed, groundwater is not used as potable water in Philadelphia. However, a potential future pathway is conservatively evaluated because an official Non-Use aquifer determination has not been made for the immediate area of the Site or Philadelphia. Since there is no official non-use aquifer determination for portion of the city around the Site, this pathway hypothetically could be considered potentially complete in the future in the absence of an environmental covenant restricting groundwater use for the following receptors:

- Indoor workers via ingestion, dermal contact, or inhalation if potable wells are installed in the absence of an environmental covenant restricting groundwater use onsite.
- Hypothetical future onsite residents via ingestion, dermal contact, and inhalation of groundwater in the absence of a deed restriction restricting the property to industrial/commercial use.

5.2.3 Future Vapor Intrusion Pathway

Based on the results of the RI Activities discussed in Section 3, in potential VI source areas (i.e., Areas 1 through 4, and select locations in the center of the Site and in the northern portion of the Fuel Blending Area), there could be complete exposure pathways for indoor workers via VI exposure from soil and groundwater if future buildings are constructed onsite without some mitigation, although these risks may

be over-predicted (see Section 3.2.6). In these areas, the VOC concentrations identified in vadose zone soil and groundwater at the Site may have the potential to cause VI concerns. Therefore, future buildings will be evaluated prior to construction to determine if a VI risk assessment and/or VI mitigation system is necessary. The results of a VI risk assessment and/or additional soil gas characterization may demonstrate or eliminate the need to install a VI mitigation system in certain areas. Alternatively, a VI mitigation system (e.g., vapor barrier) may be installed to address the potential VI pathway in lieu of performing a risk assessment. Implementation of institutional controls will provide assurance that the VI pathway is eliminated in future Site development.

6 ECOLOGICAL SCREENING

The ES evaluates potential exposure of environmental receptors at the Site. It focuses on potentially complete exposure pathways for terrestrial receptors that may be impacted by constituents of potential ecological concern (COPECs). The ES evaluates environmental conditions at the Site in accordance with the PADEP Ecological Screening Process presented in the PADEP Land Recycling Program Technical Guidance Manual (PADEP 2021). The procedure follows EPA interim final guidance on *Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments* (EPA 1997). This procedure uses eight discrete steps, with a decision option after Step 2 or Step 7 to determine whether a substantial impact has resulted from regulated substances. The information provided in this ES includes Step 1 (Fundamental Concepts) and Step 2 (Preliminary Exposure Estimate and Risk Estimate). The ES supports the use of pathway elimination as part of the scientific/management decision (SMD) concluded after Step 2. No further ecological evaluation is recommended beyond Step 2 as explained below. Under the future CSM, capping soils impacted by COPECs during site redevelopment would effectively eliminate potential ecological exposure at the Site. The requirements for Step 1 are provided in the section below, and the following section presents the findings of Step 2.

6.1 Step 1 – Fundamental Concepts

Step 1 describes the fundamental components of the Site and the environmental setting. To support Step 1, a Site visit was conducted, online ecological databases were reviewed, and appropriate regulatory agencies were consulted (via the Pennsylvania Natural Diversity Inventory receipt). Step 1 evaluates the site environmental settings and potential species and habitats of concern. The CSM is developed as part of Step 1.

6.1.1 Site Environmental Setting – Vegetation, Wetland, and Aquatic Communities

The Site environmental setting, including Site location, history, geomorphology, hydrogeology, and characterization are provided in Sections 2 and 3 of this report. The supplemental information below is provided to support the ES. It describes the vegetation and wetland communities in more detail.

Signs of observable impacts to environmentally sensitive natural areas or species were not present during the Site reconnaissance. No indication of stressed vegetation, seeps, free-product discharges, or short-term effects on biota were observed.

The vegetative communities that exist within the project area consist mostly of early successional grasslands which are dominated by invasive species, with intermittent hardwood forest mix scattered throughout the Site. Dominant vegetation within the project area includes mugwort (*Artemisia vulgaris*), orchard grass (*Dactylis glomerate*), big bluestem (*Andropogon gerardii*), eastern cottonwood (*Populus deltoides*), common reed (*Phragmites australis*), stickywilly (*Galium apartine*), and poison ivy (*Toxicodendron radicans*). A listing of vegetative species observed throughout the plant communities found at the Site is provided in Table 23.

A wetland delineation was performed at the Site on May 1, 2019. Wetlands and waters of the U.S. were identified in the field using the 1987 “U.S. Army Corps of Engineers Wetland Delineation Manual”

(USACE Manual) and the associated regional supplement for the Atlantic and Gulf Coastal Plain Region (USACE 2010). Areas within the defined project limits exhibiting wetland characteristics were flagged in the field with sequentially numbered survey tape or pin flags. The flag locations were surveyed with a handheld Trimble Geo 7X GPS. The hydrology, soils, and vegetation conditions were documented.

Six isolated wetland complexes were identified at the Site. These wetland features receive hydrology primarily from surface water flows due to their low topographic position within the landscape. Surface hydrology onsite is controlled by fill material historically placed onsite resulting in a shallow impermeable layer ranging from approximately 8 to 14 inches below the surface. Four of the wetlands are present on the western portion of the Site within a mosaic of upland and palustrine forested and emergent wetlands. A fifth palustrine emergent wetland exists as an isolated depression within the upland topography and located in the eastern portion of the Site. A sixth wetland is located within a man-made ditch associated with a retired railroad on the eastern portion of the Site. A figure showing the location of wetlands and adjacent uplands is provided in Figure 34.

Shoreline habitat at the Site consists of both man-made debris (e.g., brick, fill), former bulkhead materials, old dock cribbing, and a section of mudflat to the northern portion of the site within a man-made cove. The shoreline habitat outside of the mudflat is primarily composed of rock and gravel, with various fill materials and scatted industrial debris. The exposed mudflat is primarily covered in surface silts and no submerged aquatic vegetation was observed. Spatterdock (*Nuphar advena*) was found sparsely within the northernmost portion of the inlet feeding the cove. These shoreline habitats may provide potential habitat to common Delaware River freshwater and migratory aquatic and wildlife species (PEC 2009, PARS, 2022) such as:

- Fish species: alewife (*Alosa pseudoharengus*), blueback herring (*Alosa aestivalis*), white perch (*Morone americana*), yellow perch (*Perca flavescens*), mummichog (*Fundulus heteroclitus*), eastern silvery minnow (*Hybognathus regius*), American eel (*Anguilla rostrata*), white catfish (*Ameiurus catus*)
- Invertebrates: eastern elliptio (*Elliptio complanata*), Asian clam (*Corbicula fluminea*)
- Amphibians and reptiles: green frog (*Lithobates clamitans*), northern water snake (*Nerodia sipedon sipedon*), snapping turtle (*Chelydra serpentina*)
- Shoreline and Wading birds: great blue heron (*Ardea herodias*), spotted sandpiper (*Actitis macularius*), ring-billed gull (*Larus delawarensis*)
- Waterfowl: common merganser (*Mergus merganser*), mallard (*Anas platyrhynchos*)
- Mammals: raccoon (*Procyon lotor*), red fox (*Vulpes vulpes*)

6.1.2 Potential Species and Habitats of Concern

As introduced in Section 3.1.3, an evaluation of the potential occurrence of threatened, endangered, and/or special concern species or resources onsite was initiated through consultation with PADNR and USFWS.

The PNDI search was submitted online through the PADNR which identified the Delaware River Shoreline as a Natural Heritage Area. This habitat indicated potential species of concern "…are only found in specific areas where tidal habitat remains protected and in a few of the more naturally managed park areas." A formal review for the Site was provided by PADNR on October 2, 2019. From review of

PNDI records, the PFBC[18] indicated one threatened species of turtle (northern red-bellied cooter, *Pseudemys rubriventris*) may potentially utilize habitats occurring at the Site. PFBC indicated two unnamed endangered aquatic species. PFBC concluded in their October 30, 2019 response letter that the current Site conditions pose no adverse impacts to the species of concern. Further consultation with PFBC, via e-mail (February 2, 2022) from Arcadis, and their subsequent February 7, 2022 response letter indicated the endangered species as Atlantic sturgeon and shortnose sturgeon. Further discussion of these two species and their potential to utilize the site shoreline habitat is provided in Subsection 6.1.2.2. No other species of concern were indicated by PADNR agencies or USFWS. In their February 7, 2022 response, PFBC concluded that there will be no adverse impact to these sturgeon species from the site cleanup and identifies recommended best management practices (BMPs) to prevent potential sediment releases or changes to water quality in the waterway. The PADNR and PFBC consultation correspondence (including the 2022 correspondence) is provided in Appendix M. Following Site development, species or habitats of concern will be further protected from remaining environmental residuals at the Site.

6.1.2.1 Northern Red-Bellied Cooter Habitat Evaluation

On November 12, 2019, Arcadis performed a cover-type and habitat evaluation, searching for potential northern red-bellied cooter habitat. Observations were documented in a field book and accompanied by a photograph log (Appendix N). Active red-bellied cooters and indications of this species' presence (e.g., nests) were not identified during the survey. Site observations indicated limited basking habitat areas along the near-shoreline tidal areas. Based on the nature of the historic fill found throughout the surface layer of the upland portions of the Site, suitable nesting habitat of sandy and silty loam soils was not identified.

Subsequent ecological evaluation performed by a consultant for BPB [Herpetological Associates, Inc.] is summarized in a Phase 1 Aquatic and Nesting Habitat Survey Report. Herpetological Associates, Inc. performed the habitat survey on May 25, 2021, during the cooter's nesting season. The evaluation followed the stepwise process outlined in PADEP Land Recycling Program Technical Guidance Manual and EPA interim final guidance. Active red-bellied cooters and indications of this species' presence (e.g., nests) were not identified during the survey. The evaluation revealed potential core aquatic habitat within the Delaware River and limited basking habitat in near-shore areas. It identified three limited upland areas that are potentially suitable nesting habitat areas. These limited nesting areas appear to have marginal value and limited exposed sands. Use of pre-construction BMPs, such as turtle exclusion fencing along the entire eastern limit of redevelopment disturbance will prevent turtle nesting within active construction areas. An additional BMP, such as performing construction after the nesting season, may be used when capping the eastern portion of the former fuel blending area (i.e., the area between the railroad tracks and the Delaware River). The Phase 1 Aquatic and Nesting Habitat Survey Report is provided in Exhibit 2.

6.1.2.2 Sturgeon Habitat Evaluation

Both sturgeon species are classified as diadromous, which means that they use both fresh and saline waters during their life span. The following provides life histories and potential usage of the Delaware River habitats and likelihood to utilize the site shoreline (i.e., limited mudflat habitat).

[18] The PFBC has jurisdiction for aquatic species in Pennsylvania.

Atlantic sturgeon are hatched in the freshwater of rivers, and head out to sea as sub-adults, and return to their birthplace to spawn, or lay eggs, when they reach adulthood (ASSRT 2007). Atlantic sturgeon typically spawn between April and May in the mid-Atlantic region (CWFNJ 2022a). In the Delaware River, Atlantic sturgeon are known to spawn as far upstream as Levittown to near Morrisville, PA (CWFNJ 2022a), which are approximately 17 to 22 nautical miles upstream from the Site. Within rivers, the prime spawning areas consist primarily of cobble gravel, coarse sand, and bedrock outcrops, which occur in rapids (ASMFC 2022). This habitat provides Atlantic sturgeon with well-oxygenated water, clean substrates for egg adhesion, crevices that serve as shelter for post-hatch larvae, and macroinvertebrates for food (ASMFC 2022). After spawning occurs, adults migrate back out to brackish and saline coastal waters. Post-larval and juveniles (those less than 2 years old) migrate down or inhabit estuarine waters, with the stretch of river between the Marcus Hook Anchorage and the mouth of the Schuylkill River, PA known as a critical concentration area (CWFNJ 2022a). The upper most portion of this rearing habitat area is approximately 11 nautical miles south of the Site.

Juveniles have been found mostly over sand substrates, but also over rocks, cobble, and mud (ASMFC 2022). Juveniles tend to congregate in deep waters, particularly in the summertime (ASMFC 2022). Young sturgeon primarily use brackish water habitats and large juveniles are found in areas where the salinity exceeds 3 parts per thousand (ppt) (ASMFC 2022). Dissolved oxygen is a very important water quality parameter for Atlantic sturgeon because they show unusually high susceptibility to low oxygen (ASMFC 2022).

Shortnose sturgeon can be classified more specifically as a freshwater amphidromous species. This means that it spawns and remains in freshwater for most of its life cycle but spends some of their time in saline waters (CWFNJ 2022b). River mouths, tidal rivers, estuaries, and bays serve as prime habitat for the shortnose sturgeon (CWFNJ 2022b). Spawning typically occurs during late March into May (depending on the water temperature), when adults move to the Delaware River's non-tidal water near Scudder Falls, just north of Trenton, NJ (NJFW 2005), approximately 22 nautical miles upstream from the Site. Adults leave the spawning grounds while the young remain in the upper freshwater portion of the river for up to two weeks, then drift downstream until they reach a slow flow area suitable for feeding (NJFW 2005). Their travel continues downstream until they reach the adult foraging area in the lower part of the river (NJFW 2005), which is the tidal portion of the river near Philadelphia where they remain through May (CWFNJ 2022b). By the end of June, the sturgeon may move upstream to the area near Trenton, NJ and remain there for the summer and winter (CWFNJ 2022b). Additionally, more recent studies suggest that some shortnose sturgeon are using a second overwintering area, located in the lower portion of the river below Wilmington, DE (CWFNJ 2022b). In addition, results from a preliminary tracking study of juvenile shortnose sturgeon suggest that the entire lower Delaware River from Philadelphia (approx. rkm1 161) to below Artificial Island (rkm 79) may be used as an overwintering area by juvenile shortnose sturgeon (ERC 2006). Habitat utilization found from the study capture areas used to collect juvenile shortnose sturgeon, indicated preference to deeper stratum (i.e., 8.1-15.2 meters) (ERC 2006).

Based on the sturgeon species use of the Delaware River, adult and juvenile movements, and habitat utilization information, the potential for usage of the mudflat in front of the Site is expected to be insignificant. In addition, since in-water construction activities are not planned for the site development, potential impacts to the species are not expected.

6.1.3 Ecological Conceptual Site Model

The CSM identifies exposure pathways and potential receptor populations that may be exposed to COPECs in environmental media. Potential ecological receptors can be exposed directly or indirectly (i.e., through the food web) to COPECs if a complete exposure pathway exists. A complete exposure pathway includes the following elements: (1) constituent source; (2) release mechanism to the environment; (3) transport medium; (4) receptor contact at the exposure point; and (5) exposure route. If an element is missing, the exposure pathway is considered incomplete and is generally excluded from evaluation. Important features that need to be considered when evaluating whether an exposure pathway is complete include the COPEC concentrations in different media and their respective locations, the physical and chemical properties of the COPECs, and the locations of environmentally sensitive areas.

The CSM identifies ecological receptors and potential exposure pathways (e.g., ingestion of constituents in soil or food, direct contact with impacted media). For wildlife (i.e., birds and mammals), oral exposures are predominantly considered. Potential risks from substances via inhalation or dermal exposures are typically not quantified for wildlife because of the lack of acceptable methodology to quantify exposure.

Preliminary ecological exposure pathways were evaluated during the Site visits. No visible seeps and/or springs were observed within the upland portion of the Site. No significant surface water drainages are present. No significant surface erosion patterns in surface soils are present. Surface water runoff from the Site into the river is also limited by the relatively flat topography and vegetated surfaces near the shoreline, which also protect river surface water quality. Therefore, shallow groundwater, surface water, and subsurface soil (defined as greater than 2 feet bgs) are not considered complete exposure pathways and are not part of the CSM, leaving surface soil as the only potential pathway. Additionally, an evaluation of COPECs that may have migrated from upland source areas to sediment were not evaluated as part of the CSM because probing revealed no observable impacts to the sediment from organics. Inorganics found in sediments are expected to be consistent with Delaware River nominal background concentrations within this industrialized section of the tidal river. As shown in the CSM diagram (Figure 35), only terrestrial habitats were evaluated per existing complete or potentially complete exposure pathways from surface soils.

Under future conditions, it is expected that sources of environmental contaminants will be isolated or removed during redevelopment, thereby mitigating potential ecological exposure pathways.

6.1.3.1 Ecological Receptors

Limited wildlife species (i.e., ecological receptors) were observed onsite. Based on the disturbed nature of the habitat and industrial setting surrounding the Site, the primary wildlife species that may utilize the Site include those common species adapted to fragmented habitats found in urban landscapes (e.g., common grackle, crow, deer mice, house finch, meadow voles, mourning dove, rabbits, raccoons, robins, squirrels, and woodchucks). Species observed during the Site visits are summarized in Table 24. The following ecological receptor groups are identified for evaluating potential exposure within the current CSM:

- Plants
- Soil invertebrates
- Wildlife (e.g., American robin, meadow vole, short-tailed shrew, red fox, red-tailed hawk)

6.1.3.2 Ecological Exposure Pathways

Potential exposure routes associated with surface soil, as defined as the top 2 feet within the PADEP Ecological Screening Process, include direct contact, ingestion, inhalation, and food-web transfer. The COPECs identified in soil each possess varying degrees of potential for exposure depending on chemical-specific parameters. The following complete or potentially complete exposure pathways were identified:

- Direct contact with COPECs in soil is a potentially complete exposure pathway for wildlife and a complete exposure pathway for terrestrial plants and soil invertebrates. However, soil chemistry and nature of historical fill components may limit the potential bioavailability for some COPECs. Wildlife may have direct exposure to soil while burrowing and/or preening; however, fur or feathers greatly reduces the potential exposure.
- Incidental ingestion of COPECs in soil is a potentially complete exposure pathway for soil invertebrates and a complete exposure pathway for wildlife. Soil-bound COPECs may be ingested during foraging or grooming activities.
- For COPECs in soil that are potentially bioaccumulative, food-web transfer is a potentially complete exposure pathway. These COPECs can accumulate in soil invertebrates and plants, potentially allowing constituents to accumulate in lower trophic level organisms. In turn, mammalian and avian wildlife could consume these COPECs in their diet.

Under the future CSM, exposure routes associated with impacted surface soil would be addressed during the remedial design process and subsequent redevelopment phase, thereby eliminating the current exposure pathways.

6.2 Step 2 – Preliminary Exposure Estimate and Risk Assessment

Step 2 is the Preliminary Exposure Estimate and Risk Estimate. Under Step 2, surface soil data are compared to ecotoxicological screening benchmarks (ESBs) to evaluate the exposure and risk to ecological receptors.

Surface soil data are compared to ESBs to evaluate the exposure and risk to ecological receptors. The ecological screening process identified a total of 62 potential COPECs, including 17 metals (including cyanide), 6 pesticides, 9 VOCs, 26 SVOCs (primarily PAHs and phenol), and PCBs. The initial COPEC screening of available surface soil data collected at the Site is provided in Appendix O.

A risk characterization was conducted by comparing COPEC exposure point concentrations (EPCs) to conservative ESBs. The derived value is identified as a hazard quotient (HQ). An HQ less than or equal to 1 indicates the potential for adverse effects to ecological receptors is absent or minimal and additional evaluation is likely not necessary. An HQ greater than 1 indicates a potential for adverse effects to ecological receptors may exist and that additional evaluation of potential risks may be necessary. Using the ESBs derived for plants, soil invertebrates, and wildlife the highest HQs for COPECs were found for metals (aluminium, chromium, cyanide, iron, lead, mercury, and zinc), individual PAHs (anthracene, benzo(a) pyrene, fluoranthene, phenanthrene, and pyrene), and total PCB Aroclors. For each COPEC identified, the HQ values is provided in Appendix O.

6.3 Conclusions

Under the PADEP ES Process framework, a SMD is made to determine if:

1. The ES should be continued to develop a site-specific clean-up goal, or to reduce uncertainty in the evaluation of risk and impact.
2. The preliminary screening is adequate to determine that no substantial risk exists.
3. There is substantial impact and remediation can eliminate or reduce exposure to an acceptable level.

The results of the ES indicate potentially complete exposure pathways for ecological receptors exposed to COPECs in surface soil. However, through pathway elimination as provided in the Cleanup Plan, future ecological exposure would generally be eliminated. Therefore, no further ecological evaluation is recommended or required to reach this remedial decision.

7 PUBLIC BENEFITS TO REMEDIATION AND REUSE

The Site is ideal for a variety of commercial or industrial uses and Site development will benefit the public in various ways. The Site is being considered for commercial warehousing (see preliminary plans in Exhibit 1). The primary economic and health benefits gained by Site redevelopment are directly related to returning the property to a functional use. Site development will generate the following benefits to the Bridesburg area:

- Increased employment opportunities for the Bridesburg borough and the surrounding communities. Per a September 2019 US Bureau of Labor Statistics Report, Philadelphia County has the highest unemployment rate in the Philadelphia-Camden-Wilmington Metropolitan Area.
- Increased revenues to the Bridesburg borough. The Site is in a Federally Qualified Opportunity Zone. Opportunity Zones are a community investment tool established by Congress in the Tax Cuts and Jobs Act of 2017 to encourage long-term investments in low-income urban and rural communities nationwide.

8 REMEDIAL INVESTIGATION CONCLUSIONS

The RI was undertaken to assess the nature and extent of Site-related environmental impacts remaining after the extensive soil remediation performed as part of the RCRA closure from 1982 to 1994. The RI evaluates the risks posed to human health and the environment by those remaining impacts that will be addressed in the Cleanup Plan.

The Initial RI activities were performed by PS&S from 2003 through 2006. Based on a review of the Initial RI results, Arcadis performed a supplemental investigation in 2018 and 2019 to: (1) confirm that Site soil conditions have not significantly changed since samples were collected as part of the Initial RI activities; (2) fill identified data gaps from previous investigation and remedial actions for purposes of developing a Cleanup Plan; and (3) assess current groundwater conditions. The Site is unoccupied, and no Site use or redevelopment activities were performed between the Initial RI and the SRI. When combined, work activities performed for the RI consisted of the following:

- Excavating 197 test pits and collecting soil samples from 145 test pits.
- Installing 179 soil borings and collecting soil samples from 150 soil borings.
- Installing and sampling 33 shallow groundwater monitoring wells, 13 deep groundwater monitoring wells, and 7 hydropunch borings.
- Analyzing approximately 540 soil samples and 112 groundwater samples for a combination of TCL VOCs, TCL SVOCs, PP metals, TAL inorganics, cyanide, pesticides, and PCBs.
- Collecting 21 soil gas samples and one ambient air.
- Performing sediment probing in the Delaware River and a visual reconnaissance of the shoreline for sheens, tar-like material, elevated photoionization detector readings, or other observable indications of Site-related impacts.

The RI results provide adequate data coverage across the Site to: (1) identify and delineate the environmental conditions; (2) support a CSM; (3) develop a cleanup plan; and (4) support Site redevelopment. Based on the RI results, site-related impacts are relatively limited to the center of the Site and at isolated locations on the remainder of the Site.

Based on observations of soil samples recovered from soil borings across the Site, there are three hydrogeological units above weathered metamorphic schist bedrock. Nearest the ground surface is a layer of man-made fill materials that generally meets the description of historic fill as defined in PADEP's Management of Fill Policy (Document #258-2182-773) dated January 1, 2020. The fill layer is where most soil samples were collected and where most groundwater wells are screened. A confining unit of silt and clay material underlies the fill materials and underneath that confining unit is a sand and gravel unit. Groundwater at the Site is separated into a shallow and deep zone by the silt and clay layer. The shallow groundwater zone was formed by the historical placement of fill above native surface soils. Due to the presence and characteristics of the historic fill, it is not suitable for use.

Based on the RI results, several PAHs and lead were detected throughout the Site in surface soil at concentrations typical of urban/historic fill and, at select locations, at concentrations exceeding the non-residential direct contact MSCs. 1,1-Biphenyl, 2-methylnaphthalene, and naphthalene have been identified in subsurface soil at the Site at concentrations exceeding non-residential direct contact MSCs.

Soil containing viscous tar, oil-like material, and solidified tar was observed at isolated and limited locations at the Site. Visually impacted material was generally collocated with locations exhibiting SVOCs at concentrations greater than non-residential direct contact MSCs. These limited areas have been delineated. Additionally, select VOCs, SVOCs, and inorganics were detected in soil at concentrations greater than non-residential soil-to-groundwater MSCs. Groundwater monitoring wells were installed and sampled within and downgradient of areas with soil impacts to assess the potential impact to groundwater from soil.

Outside of these isolated areas, shallow groundwater is relatively unimpacted by former Site operations. In the shallow zone, existing groundwater conditions are typical of groundwater in urban/historic fill. Groundwater impacts were generally not observed in point-of-compliance wells downgradient from impacted areas, and fate and transport modelling indicates that the limited residual groundwater impacts in the shallow groundwater zone are not migrating offsite. The absence or limited presence of site-related constituents in deep groundwater at concentrations exceeding MSCs, coupled with the mass flux evaluation, show that groundwater from the Site is not adversely affecting river surface water quality.

Taken together, the RI soil and groundwater analytical results indicate the presence of stable, residual impacts limited to defined areas within the boundaries of the Site. Based on these RI findings, PCC will prepare an Act 2 Final Report for groundwater upon PADEP's approval of the RICP.

VOCs were not detected above the screening values for non-residential, sub-slab, soil gas samples collected during the Initial RI. Additionally, a comparison of existing unsaturated soil and groundwater data to residential VI standards from the TGM indicate there are no potential VI concerns for the residential properties adjacent to the Site. However, the existing unsaturated soil and groundwater results indicate the potential for VI in future Site buildings.

The COCs for the Site are listed in Table 8-1 below.

Table 8-1: COC For Each Environmental Medium

Analyte	CAS Number	Surface Soil COC (Yes/No)	Subsurface Soil COC (Yes/No)	GW COC (Yes/No)	VI COC (Yes/No/na)
Volatile Organic Compounds					
Benzene	71-43-2	No	**Yes**	**Yes**	**Yes**
Chlorobenzene	108-90-7	No	**Yes**	No	No
Dichloromethane	75-09-2	No	**Yes**	No	No

Benzo(b)fluoranthene	205-99-2	**Yes**	**Yes**	**Yes**	na
Benzo(g,h,i)perylene	191-24-2	No	**Yes**	**Yes**	na
Benzo(k)fluoranthene	207-08-9	**Yes**	**Yes**	**Yes**	na
bis(2-Ethylhexyl)phthalate	117-81-7	No	No	**Yes**	na
Carbazole	86-74-8	No	**Yes**	**Yes**	na
Chrysene	218-01-9	**Yes**	**Yes**	**Yes**	na
Dibenz(a,h)anthracene	53-70-3	**Yes**	**Yes**	**Yes**	na
Dibenzofuran	132-64-9	No	**Yes**	**Yes**	na
Fluoranthene	206-44-0	No	**Yes**	No	na
Fluorene	86-73-7	No	**Yes**	No	na
Indeno(1,2,3-cd)pyrene	193-39-5	**Yes**	No	**Yes**	na
Naphthalene	91-20-3	**Yes**	**Yes**	**Yes**	**Yes**
Phenanthrene	85-01-8	No	**Yes**	No	na
Phenol	108-95-2	No	**Yes**	No	na
Pyrene	129-00-0	No	**Yes**	No	na
Inorganics					
Antimony	7440-36-0	No	**Yes**	**Yes**	na
Arsenic	7440-38-2	**Yes**	**Yes**	**Yes**	na
Cyanide	57-12-5	No	**Yes**	No	na
Lead	7439-92-1	**Yes**	**Yes**	No	na
Manganese	7439-96-5	No	No	**Yes**	na
Mercury	7439-97-6	No	**Yes**	No	na
Nickel	7440-02-0	No	**Yes**	**Yes**	na
Selenium	7782-49-2	No	**Yes**	No	na
Vanadium	7440-62-2	No	No	**Yes**	na
Pesticides					
Dieldrin*	60-57-1	No	No	**Yes**	na

Notes: na = not applicable analyte does not readily volatilize; GW = groundwater; the inorganics shown for groundwater are based on dissolved-phase analytical results. * = 2,4-Dinitrotoluene and dieldrin concentrations are attributed to background conditions.

Currently, there is no complete exposure pathway to impacted soil and groundwater. Future exposure pathways via direct contact with Site soil or groundwater for incidental ingestion, direct dermal contact and/or inhalation of windblown particulates (fugitive dusts) or volatilized COCs will potentially be complete if no controls are implemented.

Based on the concentrations of select COCs in unsaturated soil and groundwater, there is potential for a complete VI exposure pathway when buildings are constructed onsite in the future. The potentially complete exposure pathway would be for indoor occupants, residents, and workers via VI from soil and

groundwater if future buildings are constructed onsite in the absence of engineering and institutional controls.

The findings of the RI provide the basis for performing a “pathway elimination” cleanup approach.

9 CLEANUP PLAN

The NIR was submitted to PADEP stating that PCC is seeking a release of liability under the Act 2 Site-Specific Standard (Appendix A). Current potentially complete exposure pathways and hypothetical future exposure pathways (without engineering and institutional controls) are presented in Section 5 and summarized in Table 9-1 below:

Table 9-1: Summary of Current and Hypothetical Future Exposure Pathways

Current and/or Future Exposure Pathway	Potential Current Receptors	Potential Future Receptors without Remedy
Incidental Soil and GW Ingestion, Dermal Contact, and Inhalation of VOCs and Particulates	1. Utility/Construction Worker 2. Outdoor Worker	1. Resident 2. Recreational User 3. Building Occupant 4. Utility/Construction Worker 5. Outdoor Worker 6. Trespasser
Potable Water Ingestion and Use	None	1.Resident 2.Building Occupant 3.Indoor Worker
Soil Vapor Intrusion	None	1. Resident 2. Building Occupant 3. Indoor Worker

Based on the characterization data for soils and groundwater presented in Section 3 and review of migration pathways and potential receptors, the remedial action objective for the Site is to protect human health by eliminating identified exposure pathways with soils and groundwater impacted by VOCs, SVOCs, and inorganics. The Cleanup Plan:

- Provides methods to achieve pathway elimination for impacted soils using engineering controls (e.g., capping of soils with structures, roadways, parking lots, and landscaping).
- Outlines procedures and plans to allow for safe execution of proposed Site redevelopment activities.
- Specifies institutional controls to be implemented (i.e., Environmental Covenants, restrictions, or other appropriate vehicles).
- Outlines a PRCP.

The proposed Site-Specific Standard for this Site generally consists of “pathway-elimination,” which means that potentially complete future exposure pathways will be mitigated using engineering and/or institutional controls. Details of site-specific engineering controls will be updated in the future if and as Site development occurs. Engineering controls proposed in this Cleanup Plan include:

1. Covering impacted soils with asphalt/concrete pavement, building structures, and/or a minimum 2-foot thick clean soil cover to prevent direct contact exposure and/or to mitigate potential migration of constituents from soil-to-groundwater. The soil cap will cover areas where constituent concentrations in soil exceed the non-residential direct-contact standards and the soil-to-groundwater MSCs. With

the exception of the existing railroad, the entire Site will be capped by various methods to meet the Site-Specific Standard via a "pathway elimination".

2. Employing VI mitigation measures for future buildings constructed onsite if and where needed. An initial screening of areas with potential VI concerns is provided as Figure 36. Additional soil gas characterization and/or a cumulative risk assessment may demonstrate that mitigation measures are not needed.

Proposed institutional controls are a deed restriction/environmental covenant that: (1) prohibits use of groundwater at the Site; (2) restricts the Site to non-residential use; and (3) requires a PRCP that stipulates inspection, periodic maintenance/repair activities, and reporting requirements for engineering controls, as appropriate. These restrictions will be embodied in a recorded and enforceable Environmental Covenant.

This Cleanup Plan may be implemented in conjunction with Site redevelopment. Surface elements of redevelopment, such as paving, building foundations and slabs may be used to form an integral part of the planned final cap for the Site and eliminate potential exposure pathways. The Cleanup Plan may be implemented using an iterative process that results in elimination of potential exposure pathways as any potential redevelopment is conducted; however, the general remedial scheme will be implemented even in the absence of redevelopment.

PCC sold the property to BPB on March 30, 2022. BPB will be redeveloping the Site in conjunction with PCC's site cleanup.

- Figure 29: Groundwater Monitoring Wells Exhibiting Potential Vapor Intrusion Concerns
- Figure 36: Site Locations with Potential Vapor Intrusion Concerns
- Figure 37: Soil Cap Limits
- Figure 38: Location of TSCA Regulated Soils

A comprehensive list of report figures is included in the table of contents, and figures are referred to throughout the text.

9.3 Remedial Goals

Based on the analysis of remedial alternatives presented herein, the remedial goals for soil will be to allow historic fill and impacted soils to remain in place with capping (e.g., asphalt/concrete pavement, building structures, a minimum 2-foot thick clean soil cover), to the extent practicable, and provide new cover/capping across the Site to meet the Site-Specific Standard, as discussed below.

9.4 Remedial Alternatives

The technical guidance recommends the identification of remediation alternatives, and an evaluation of the effectiveness of the selected remedy to achieve the Site-Specific Standards, based on the factors set forth in Section 304(j) of Act 2. The evaluation should consider: 1) the long-term risks and effectiveness; 2) the ability of the remedy(ies) to reduce the toxicity, mobility or volume of regulated substance; 3) the short-term risks and effectiveness; 4) the ease or difficulty of implementation; 5) the cost of the remedial measure; and 6) the incremental health and economic benefits of the remedy.

9.4.1 Selection of Remedial Alternatives

General response actions are broad categories of remedial technologies that can potentially be used to meet remedial action objectives. The general response actions typically include:

- Institutional Controls
- Containment
- Treatment
- Removal and Disposal

Institutional controls and containment processes reduce the risk of exposure, but do not remove or destroy the COCs.

Containment technology options are those that control the release or minimize the potential for contact. Examples of containment approaches include surface capping, vertical barriers, and horizontal barriers.

Treatment technology options are those that reduce the mobility, toxicity, or volume of the source of impacts. Treatment can employ physical, chemical, or biological methods and can be applied in-situ (in place) or ex-situ (following removal from the source location).

Removal and disposal options remove impacted media from an area of concern and relocate it to a more secure area. An example of a removal and disposal option is excavation of impacted soil and disposal in a permitted landfill.

9.4.2 Evaluation of Remedial Alternatives

The selection of an acceptable remedial alternative requires the establishment of comparison criteria that address the major factors required for successful remedial action. Additionally, a mechanism to rank the various factors is also important.

The criteria used to evaluate the retained remedial alternatives are those described in Section 304(j) of Act 2, summarized as follows:

- "Long-term Risks and Effectiveness" – The magnitude of residual risk following implementation of the alternatives are evaluated. The type, degree and duration of post-remediation care, potential for exposure, and adequacy and reliability of controls are also considered.
- "Reduction of Toxicity, Mobility or Volume" – This criterion addresses hazardous constituents, treated contaminants and residuals remaining after the remedial alternative is implemented. The degree of reduction in toxicity, mobility and volume is evaluated.
- “Short-Term Risks and Effectiveness" – During implementation, potential short-term impacts to onsite workers, adjacent residents, and the environment are considered.
- "Implementability" – Ability to construct, operate, monitor, maintain and obtain regulatory approvals for an alternative are considered. The evaluation also includes availability of technologies, equipment, trained personnel and offsite disposal services.
- "Cost" – Capital, operation and maintenance costs are estimated and evaluated. In generating these calculations, Arcadis has assumed that some construction requirements are applicable to all

remedies associated with the potential reuse of the property for development. Therefore, costs such as sediment and erosion control for each remedy would be essentially equal.

- "Incremental Health and Economic Benefits" – The long-term economic benefits are evaluated for each of the potential remedies.

The selected soil remedy, groundwater, and soil vapor remedies are summarized in the Sections 9.6 through 9.8.

9.5 Community Participation

The selected remedial alternative will be adjusted, as appropriate, based on community feedback. A Public Involvement Plan (PIP) has been prepared for the Site that defines procedures for community engagement and the communication of findings from ongoing Site remediation in accordance with the latest updates to Act 2 and the TGM. The PIP establishes the framework for educating interested parties about past and ongoing Site environmental remediation efforts and enables communication between the public, PCC, the site developers, PADEP, EPA, Philadelphia Department of Public Health, and other Philadelphia Departments and elected officials. The PIP:

- Provides public access to project documents at convenient locations.
- Designates a central point of contact to address questions from the community.
- Identifies a location for public hearings and meetings near the Site.

The PIP is available to the public at the Frankford Library and online at: http://www.4501richmondstreet.com/.

9.6 Selected Soil Remedy

The following COCs have been reported as detected in surface soil at concentrations above the non-residential direct contact MSCs for surface soil:

- SVOCs: 2-Methylnaphthalene, BaA, BaP, BbF, benzo(k)flouranthene, chrysene, dibenz(a,h)anthracene, indeno(1,2,3-cd)pyrene, and naphthalene.
- Metals: arsenic and lead.

The sampling locations where constituents have been detected in soil at concentrations greater than the non-residential direct contact MSCs are shown in Figures 18 and 19. 1,1-Biphenyl, 2-methylnaphthalane, and naphthalene were detected in subsurface soil at concentrations above the non-residential direct contact MSCs in subsurface soil. The subsurface soil COCs are presented in Table 9-3 (constituents that exceeded the non-residential and/or the soil-to-groundwater MSCs in soil samples. The number of non-residential soil-to-groundwater exceedances for each constituent is also presented vs. the total number of soil samples collected. In general, visual impacts and elevated PID readings were also observed at the same soil sampling locations that contained the highest concentrations of constituents. Figure 17 shows sampling locations where visual impacts or elevated PID readings were observed.

Table 9-3: Subsurface Soil COCs

Analyte	CAS Number	S-GW Exceedance Frequency
Volatile Organic Compounds		
Benzene	71-43-2	36/530
Chlorobenzene	108-90-7	4/530
Dichloromethane	75-09-2	5/530
Ethylbenzene	100-41-4	3/529
Styrene (Monomer)	100-42-5	2/470
Toluene	108-88-3	1/532
Semi-Volatile Organic Compounds		
1,1-Biphenyl	92-52-4	28/168
2-Methylnaphthalene	91-57-6	30/535
4-Methylphenol	106-44-5	1/296
Anthracene	120-12-7	15/535
Benz(a)anthracene	56-55-3	15/535
Benzo(a)pyrene	50-32-8	39/535
Benzo(b)fluoranthene	205-99-2	22/535
Benzo(g,h,i)perylene	191-24-2	13/535
Benzo(k)fluoranthene	207-08-9	6/535
Carbazole	86-74-8	18/535
Chrysene	218-01-9	18/535
Dibenz(a,h)anthracene	53-70-3	2/535
Dibenzofuran	132-64-9	16/535
Fluoranthene	206-44-0	8/535
Fluorene	86-73-7	4/535
Naphthalene	91-20-3	54/535
Phenanthrene	85-01-8	4/535
Phenol	108-95-2	2/535
Pyrene	129-00-0	6/535
Metals		
Antimony	7440-36-0	3/527
Arsenic	7440-38-2	101/527
Cyanide	57-12-5	3/333
Lead	7439-92-1	89/527
Mercury	7439-97-6	2/525
Nickel	7440-02-0	1/527
Selenium	7782-49-2	1/527

Note: S-GW indicates the soil-to-groundwater MSCs for a non-residential used aquifer with TDS less than or equal to 2,500 ppm

Due to the relatively low levels of COCs identified at the Site and the scattered and often isolated locations across the Site, the selected remedial alternative will be capping and/or covering of the impacted areas.

This selected remedy will:

- Significantly reduce the risk of exposure following installation of the remedy.
- Minimize the type and duration of post remediation care required.
- Significantly reduce the potential exposure to human and ecological receptors.
- Be accomplished in a reasonable period of time at a realistic cost.

While the proposed remedy does not reduce the toxicity or volume of impacted soils, the mobility of the impacted soils is significantly reduced by the proposed capping system. In addition, as noted above, the concentrations of these COCs are generally low and often isolated.

Site characteristics that may affect the implementation or effectiveness of the remedial action are as follows:

- The location of the impacted soils will dictate the mechanism for soils capping. The identified impacted soils are generally at depths less than 15 ft bgs.
- The locations of impacted soil areas will be marked prior to implementation of remedial activities in that area. Additional care will be taken if these areas need to be excavated and the disposition of excavated materials from these areas will be documented.

The short-term risks are minimal to construction workers and will be further reduced by onsite monitoring of the soil removal as discussed in Subsection 9.5.1. The short-term effectiveness of the remedy has been proven in numerous applications of a cap as a remedial alternative. The ease of implementation of the remedy has been proven in many prior instances. Commercially available equipment will be used along with established construction practices. The incremental health and economic benefits gained by implementation of the selected remedy include returning the property to a functional use with associated benefits to the community.

An Erosion and Sedimentation Control Plan (E&SC documents) will be prepared; remedial activities will not proceed without approved E&SC documents.

9.6.1 Detailed Description of Remedial Action for Soil

The selected remedial action for soils with reported detections above the non-residential MSCs will be capping of the impacted soil areas. As per the redevelopment plans, with the exception of the railroad track right-of-way (RR ROW), the entire site will be capped by new buildings, asphalt-paved driveways and parking areas, concrete sidewalks, or a minimum 2 feet of imported clean fill (for areas not covered by impervious surfaces). Asphalt pavement and buildings will significantly reduce and limit infiltration across much of the Site; stormwater runoff will be collected and conveyed offsite to the river. Potentially complete exposure pathways remain on the RR ROW, and a human health risk assessment (HHRA) has been prepared to consider these pathways. The HHRA, which is provided as Appendix P and summarized in Section 9.6.1.4, shows that there are no unacceptable risks to potential receptors. The limits of the soil cap are shown in Figure 37.

Any soil that needs to be excavated from impacted areas associated with grading, utility, or foundation installation, will be relocated and will be capped, as appropriate. If immobile tar or tar-like material is encountered during construction requiring removal from its present location, the material will be characterized and may remain onsite if found to be non-hazardous. During implementation of the remedial work (and any Site redevelopment if applicable), specific environmental controls, decontamination, health and safety requirements, and soil management, handling, and disposal requirements will need to be followed. Work conducted on the Site will be in accordance with the procedures defined in a site-specific HASP. The HASP requires construction workers that have the potential to contact impacted soil to be: (1) trained as required by Occupational Safety and Health Administration (OSHA) Regulation in 29 CFR 1910.120 (HAZWOPER); (2) medically cleared to work at the Site; and (3) medically monitored as per OSHA at 29 CFR 1910.120(f). These construction workers must use PPE to mitigate soil exposure pathways. The proposed remedial actions and associated construction requirements are summarized below.

Prior to starting any excavation at the Site, the planned excavation activities will be reviewed to evaluate if the proposed excavation will occur in areas known to contain impacts and/or areas that have the potential to contain impacts. The proposed ground-intrusive activities will be monitored if the excavation likely will encounter, or holds the potential to encounter, impacted soil. Additionally, the Site will be surveyed and staked/marked to identify areas (Areas 1 through 4 shown on Figure 20) and sampling locations where viscous tar or tar-like material was previously observed. Soil screening will be performed for visual impacts, odors, or elevated PID readings during excavations into known or potentially impacted material.

9.6.1.1 Earthwork Preparation and General Procedures

Site grading or excavation activities within marked areas will be documented to identify the relocation of any impacted soil. Soil onsite can be reused as fill in areas that will be covered as part of site redevelopment. Fill material removed from the Site, including historic fill, will be managed in accordance with PADEP's Management of Fill Policy (Document #258-2182-773), unless otherwise indicated in Subsection 9.6.1.2. Potential waste materials are discussed in Subsection 9.6.1.2.

E&SC measures will include silt fencing and/or hay bales that will be installed in appropriate locations in and around the remedial work area to minimize surface soil in the disturbed areas from potentially being transported, via wind and/or surface water, to areas outside of the limits of disturbance. If staged, impacted soil will be placed on plastic sheeting (minimum 6 mil thickness) adjacent to the excavation area and kept covered with appropriately anchored tarps when inactive, unless otherwise indicated in Subsection 9.6.1.2. Imported clean fill will be placed where necessary to suppress odors. A stockpile of clean material will be kept onsite for this use.

9.6.1.2 Soil Management

Soil that is undisturbed during Site redevelopment may remain in-place. Soil that needs to be excavated from impacted areas for site grade adjustment, utility installation, or foundation construction will be relocated and capped, as appropriate.

As indicated below, some soil and waste may need to be disposed offsite. Any soil disposed offsite will be managed in accordance with all local, State, and Federal regulations. Small quantities of waste, along with drums of used PPE and similar small debris type items, may be stored in labeled USDOT

Specification containers before onsite reuse or offsite disposal. For any materials disposed offsite, disposal quantities and associated documentation will be reported to the PADEP in the Final Report. This documentation will include waste profiles, test results, facility acceptance letters, manifests, bills of lading, and facility receipts. Waste records will contain a summary of transport tonnage and list the disposal destination. The waste manifests will be maintained onsite until submitted in the Final Report.

The handling of waste materials that may potentially be encountered during Site redevelopment is summarized by material type below.

Management of Tar/NAPL Saturated Soils

As stated in the RI, limited quantities of subsurface Site soils are impacted by viscous tar or oil-like material and associated SVOCs. The goal is to achieve Site-Specific Standards through pathway elimination to these impacted soils. Soil impacted with tar- and oil-like material remaining onsite will be left in-place unless encountered or disturbed during redevelopment activities. This material may be encountered in certain locations during grading or excavation for site redevelopment (for the installation of utilities, drainage features, and/or foundations). Sampling locations that contained viscous tar or oil-like material are shown on Figure 14.

If encountered during construction, tar-like material will be visually characterized and evaluated for the presence of free liquid by Method 9095 (paint filter liquids test), in accordance with Title 25 Chapter 287.1 of the Pennsylvania Code. The paint filter test will be performed at temperature exceeding 25°C (77°F), as recommended in EPA Method 9095B. The results of the paint filter test will inform material management, as follows:

- If no separate phase liquid is present (indicating immobile tar or tar-like material) and the material requires removal from its present location, the material will be sampled for RCRA waste characteristics. The material may remain onsite if found to be non-hazardous.
- If separate phase liquid is present (indicating potentially mobile tar or tar-like material), the tar/soil mixture will be segregated and transferred to a material staging area constructed with a low-permeability liner system (e.g., high-density polyethylene [HDPE]) extending over the prepared ground surface and formed sidewalls. The stockpiled material will be characterized to determine disposal requirements and subsequently disposed of offsite in accordance with 25 Pa. Code Sections 250.3(a).

TSCA-Regulated Waste

As discussed in Section 3.2.4, an EPA approved Self-Implementing Cleanup Notification for PCB Remediation Waste was prepared for the Historical Tar Plains/Fill Area. Soil within the Historical Tar Plains/Fill Area will be managed in accordance with the Self-Implementing Cleanup Notification. At a minimum, any soil that needs to be excavated from the Historical Tar Plains / Fill Area because of grade adjustment, utility installation, or foundation work will be relocated, consolidated, and capped within the Historical Tar Plains / Fill Area. Soil originating from the Historical Tar Plains / Fill Area will not be relocated outside the limits of this area for consolidation. If soil needs to be removed from the Site (e.g., from the area of PSSTP-01A, for geotechnical reasons), it will be characterized and disposed of at a facility permitted to accept the material. Any soil leaving the Historical Tar Plans / Fill Area will be characterized for PCBs. Based on analytical data, geotechnical data, and current redevelopment plans,

soil in the Historical Tar Plains / Fill Area will not need to be excavated. The location of the Historical Tar Plains / Fill Area is shown on Figure 38.

Former Operations Piping

If required during redevelopment activities, former operation piping will be removed and placed in appropriate waste management containers or transferred to a material staging area constructed with a low-permeability liner system (e.g., HDPE) extending over the prepared ground surface and formed sidewalls, to contain potential liquids. Sludges, residues, or fluids other than groundwater will be removed from the piping by gravity draining into appropriate waste management containers and taken offsite. The removed material will then be disposed offsite at an appropriate disposal facility in accordance with all local, state, and federal regulations.

Any discovered tar or tar-like material from pipe material will be handled as detailed earlier in this subsection. If analytical results identify an unknown or unexpected source material, the results will be promptly communicated by phone to PADEP's Project Manager.

The location, description, management, and disposal of any subsurface piping discovered during redevelopment will be noted in the Final Report (submitted to the PADEP).

9.6.1.3 Soil Capping System

When constructing the soil cap, soil sampling locations that contain COCs at concentrations greater than direct contact MSCs will be surveyed and marked, as appropriate. The capping of impacted soil areas, either by asphalt/concrete paving, building slabs, or soil cover will be documented. The soil cap will be Site-wide, and at a minimum will extend across areas of the Site where: (1) COCs are in soil at concentrations greater than the non-residential soil-to-groundwater and direct contact MSCs (see Figures 18 and 19); and (2) excavated soil impacted by COCs is reused onsite (unless laboratory analytical data demonstrates that COCs do not exceed non-residential direct-contact MSCs for surface soil). Final cap across the Site will be constructed in accordance with the PADEP draft guidance entitled, "The Use of Caps as Activity and Use Limitations" and consist of:

- Two feet of clean fill, including landscaping topsoil, in the greenspace and other landscaped areas underlain by a geotextile fabric to serve as a visual distinction between the clean fill cap and the existing impacted soil; or
- Site paving, building foundations and floor slabs.

The minimum 2-foot cap thickness will be verified by use of land surveying to document that cap design elevations and grades are achieved across the site consistent with grading plans. The soil cover will be placed and compacted under the supervision of a licensed geotechnical engineer to ensure long term settlement will not exceed tolerances required to provide a minimum of 2 feet of soil at all times.

A minimum 2-foot thick cap transition to the property boundaries and railroad right of way will be installed as shown in Exhibit 4. The cap transition involves grading existing soil so that when 2 feet of clean fill is placed, the surface elevation of the new cap matches the ground surface elevation at the property boundary. The cap thickness will be 2 feet within the entire transition area. Grading to achieve this transition will require removing existing soil from the cap boundaries. Removed soil will be managed as discussed in subsection 9.6.1.1.

A wetland mitigation area is being created near the southeast corner of the Site, as shown in Exhibit 5. This wetland will be established by over-excavating the existing soil to install two feet of clean capping material that will support wetland vegetation. Additionally, a wetland in the northeast corner of the Site is being covered by 2 feet of soil and reestablished. This wetland may be over-excavated to install 2 feet of clean fill to maintain appropriate Site grading. The wetland will be constructed in accordance with applicable permits submitted to and approved by the PADEP Bureau of Waterways Engineering and Wetlands.

A PRCP (institutional control) has been developed for long-term care and maintenance of the final cap(s), and it is presented as Exhibit 3.

9.6.1.4 RR ROW HHRA Summary

An HHRA has been prepared for the RR ROW where the existing ground surface will be unimproved as per an easement that must permit the continuous operation of the Philadelphia Beltway Railroad, although the railroad is currently inactive. The HHRA is provided in Appendix P. The HHRA evaluated anticipated future potential human health exposure to COCs in surface soils at the RR ROW. The analytical results for surface soils collected within 30 feet of the RR ROW were compared to the USEPA Regional Screening Levels (RSL) for industrial soil at total risk levels of $1x10^{-6}$ and total hazard quotient of 0.1. Benzene, PAHs, metals, and Aroclor 1260 were detected at concentrations exceeding RSLs and identified as COCs. Utilized EPCs were the calculated 95% upper confidence limits or maximum detection depending on each COC dataset. Outdoor site workers and adolescent trespassers were evaluated as the future site receptors in the HHRA. A toxicity assessment was performed following PADEP and EPA recommended hierarchy. A combination of default and conservative site-specific exposure assumptions were identified for each receptor (e.g., exposure frequency = 50 days/year; adolescent exposure duration = 9 years or age range 12 to 21). Risk characterization and calculations were conducted following methodology consistent with PADEP Act 2 and EPA approaches to human health risk assessment. Carcinogenic risks for the adolescent trespasser and outdoor site worker were within EPA's target risk range of $1x10^{-6}$ to $1x10^{-4}$. Non-cancer hazards for the adolescent trespasser and the outdoor worker were all less than the USEPA target of 1.

Although not considered for this cleanup plan, potential exposure pathways along the RR ROW are anticipated to be the eliminated as part of Pennsylvania Department of Transportation's (PennDOT) Delaware Avenue Extension project. As early as 2024, PennDOT intends to construct a new road and railroad. PennDOT plans to build the new infrastructure on imported fill and limit excavations as much as possible. To support the project, PennDOT has contracted with CDM Smith to facilitate a soil and geotechnical investigation along the proposed alignment of the new infrastructure. Project work will be conducted by 40-hour OSHA Hazwoper trained personal following the most current draft of the PRCP. A map showing the proposed Delaware Avenue extension and railroad alignment is provided as Exhibit 6. The proposed layout includes a new 150-foor ROW for the road and a new alignment for the RR ROW.

9.6.1.5 Shoreline Improvements

The rubble-armored seawall at the waterfront will be improved. R-5 riprap stone will be used to stabilize the area above the existing shoreline wall. This stone will be placed at the top of the wall and will cover an area that extends 6 feet back from the top of the wall. BPB is currently planning to excavate and remove the existing concrete outfall pipe and replace it with a 36-inch diameter HDPE pipe in the same

trench/alignment. The outfall of the new HDPE pipe will be set inland approximately 50 feet from the current outfall location so that it will not disturb the mudflat area. Outlet protection will be installed, consisting of a custom headwall surrounded by a rip-rap (rock) apron. The new outfall pipe will be equipped with backflow prevention and a trash rack. Outfall details are presented in Drawing 3 of Exhibit 7.

Additionally, BPB is planning a greenspace setback of approximately 350 feet or more from the shoreline which exceeds the 100-meter setback recommended in the 2008 Natural Heritage Inventory of Philadelphia County (Inventory; Pennsylvania Natural Heritage Program 2008). The Inventory also recommends that the existing small tidal marsh (wetland) between the northern pier and marina to the north is “enhanced by removing obstructions to flooding in this low-lying area, increasing the potential for tidal marsh development.” BPB is proposing to establish a new wetland in the southeast corner of the Site that will be tidally connected to the mudflats area, increasing the current ecological value in the shoreline area.

9.6.1.6 Stormwater Management

BPB has used the Permit Application Consultation Tool PACT and submitted a “draft” National Pollutant Discharge Elimination System NPDES permit to PADEP, seeking approval to manage the stormwater, wetlands, and waterway requirements onsite. As part of the permitting effort, BPB is developing a stormwater management plan for the proposed redevelopment. Stormwater runoff will be collected in permanent lined basins (lined with a 30 mil geomembrane) and conveyed offsite (stormwater management will not rely on infiltration). In addition, the former main production area will be covered by the building and parking lots, including the area near and upgradient from PCMW-09D where deep groundwater may be impacted. Therefore, the potential pathway for soil impacts to migrate to groundwater will be further limited by the proposed site redevelopment.

During redevelopment, temporary sediment basins will be installed at the approximate location of the planned permanent stormwater basins. The temporary basins will be lined with a 30-mil geomembrane meeting the same requirements as the liner used for the future permanent basins. The temporary stormwater basins will be inspected monthly and after rainfall events exceeding 3 inches within 24 hours for indications of a compromise to remedial measure integrity (e.g., excessive settlement, erosion). The inspections will be documented on an inspection log and maintained at the construction site. Required repairs will be made by qualified personnel and recorded on an Intrusive Work Notification and Documentation form. Completed forms will be maintained in onsite files. A narrative description and/or plan mark-up depicting the cross sections and details of the remedial measures will be documented in the inspection logs for any necessary repairs. The temporary basins will remain in place for a period of 10 to 14 months before being converted to permanent stormwater basins. The process of conversion will occur in series over a period of 4 to 6 weeks in which all sediment will continue to be managed onsite according to Philadelphia Water Department and PADEP best management practices.

9.6.1.7 Best Management Practices for Ecological Receptors

Using PFBC’s recommendations, the construction plan will include standard BMPs to be implemented to address runoff to surrounding waters. The BMPs to be implemented during construction will be protective of potential habitat for threatened or endangered species that may use this area. BMPs such as turtle exclusion fencing along the entire eastern limit of redevelopment disturbance will prevent turtle nesting

within active construction areas. An additional BMP, such as performing construction after the nesting season, may be used when capping the eastern portion of the former fuel blending area (i.e., the area between the railroad tracks and the Delaware River).

9.6.1.8 Work Under the Soil Cap

Future work activities beneath the cap will be performed in accordance with a PRCP (Exhibit 3). For ground intrusive work below the cap, a HASP will be followed to prevent exposure to future workers (for repairs to utilities, building expansion, etc.). The HASP would require construction workers that have the potential to contact impacted soil to be: (1) trained as required by occupational safety and health administration (OSHA) Regulation in 29 CFR 1910.120 (HAZWOPER); (2) medically cleared to work at the Site; and (3) medically monitored as per OSHA at 29 CFR 1910.120(f).

Alternatively, an HHRA may be developed that evaluates potential risks to construction workers. The results of an HHRA would evaluate the required safety procedures required for subsurface work under the cap and whether ground-intrusive work can be performed without 40-hour OSHA Hazwoper training.

Utility workers installing or maintaining subsurface utilities are reasonably anticipated future receptors and may be exposed to soil underneath the capping system. Therefore, the PRCP includes an HHRA for the utility worker performing 10 days of work each year under the soil cover. Site-wide analytical data for surface soil (future subsurface soil underneath the capping system) and unsaturated subsurface soil were compared to the USEPA Regional Screening Levels (RSL) for industrial soil at total risk levels of $1x10^{-5}$ and total hazard quotient of 1. Several VOCs, SVOCs, metals, and PCBs were detected at concentrations exceeding RSLs and identified as COCs. Version 5.1 of EPA's pro-UCL software was utilized to calculate the upper confidence limits for the COC list. A toxicity assessment and risk calculations were performed following PADEP and EPA guidance. The HHRA concludes that total excess lifetime cancer risks are below the target risk of 1×10^{-5} and that total non-cancer hazards are less than the USEPA target of 1.

9.7 Selected Groundwater Remedy

The following have been reported as detected in groundwater at concentrations above the PADEP non-residential MSCs for Used Aquifers containing TDS ≤ 2,500 mg/L:

- VOCs: benzene, MTBE, tetrachloroethene, TCE
- SVOCs: 1,1-biphenyl, 2,4-dinitrotoluene, 2-methylnaphthalene, BaP, BbF, benzo(g,h,i)perylene, benzo(k)fluoranthene, bis(2-ethylhexyl)phthalate, carbazole, and chrysene.
- Total Metals: antimony, arsenic, beryllium, lead, manganese, nickel, and zinc.
- Dissolved Metals: antimony, arsenic, manganese, and nickel.

VOCs and SVOCs detected in groundwater at concentrations greater than MSCs are shown in Figure 25, and dissolved inorganics detected in groundwater at concentrations greater than MSCs are shown in Figure 26. In general, SRI groundwater data indicates that groundwater conditions are improving across the Site, especially in regard to VOCs and SVOCs in replacement wells, and groundwater impacts are isolated and limited in extent.

Due to the relatively low levels of COCs identified at the Site and groundwater data from point-of-compliance wells showing that impacted groundwater is not migrating offsite, an Environmental Covenant prohibiting onsite groundwater use for any purpose is the selected remedy. The EC will also restrict Site use to non-residential use. Such a restriction will ensure that exposure to groundwater from beneath the Site does not occur. With groundwater use prohibited, there will be no future complete exposure pathway to groundwater at the Site. Appropriate institutional controls are proposed to effectively mitigate the complete exposure pathways listed in Section 5.

This selected remedy will:

- Significantly reduce the risk of exposure following establishment of the institutional controls.
- Minimize the type and duration of post-remediation care required.
- Significantly reduce the potential exposure to human and ecological receptors.
- Be accomplished in a reasonable period of time at a reasonable cost.

Construction or utility workers may encounter shallow groundwater during utility excavations for installation, maintenance, or repair of underground utilities. Volatile constituents in groundwater may volatilize into the utility trench. If future excavation were to be required to the depth of the perched water or groundwater table, the procedures listed in Subsection 9.6.1.8 will be followed to limit construction worker exposure from groundwater impacts.

Groundwater monitoring wells will be decommissioned using the grout-in-place method in accordance with applicable regulatory requirements. Upon approval of this RI Report and Cleanup Plan, an Act 2 Final Report for groundwater will be prepared

9.8 Soil Vapor Remedy

VOCs were not detected at concentrations above the non-residential sub-slab screening values in subsurface soil gas samples collected during the Initial RI. As discussed in Section 3.2.6, soil and groundwater analytical results likely overpredict VI potential because the soil gas sampling results did not exceed any of the sub-slab VI screening values. However, a comparison of existing unsaturated soil and groundwater data to non-residential VI standards from the TGM indicates the potential for soil VI if buildings are constructed in the future. The following constituents have been detected in soil and/or groundwater samples at concentrations above non-residential VI standards: benzene, MTBE, TCE, toluene, 1,1-biphenyl, 2-methylnaphthalene, and naphthalene. A detailed analysis of the VI COCs is included in the VI Evaluation provided as 3.2.6.

Unsaturated soil sampling locations where COCs have been identified at concentrations exceeding the non-residential VI standards are shown in Figure 28 and groundwater sampling locations where COCs have been identified at concentrations exceeding the non-residential VI standards (or for groundwater within 5 feet of the ground surface, the non-residential MSCs for used aquifers containing TDS ≤ 2,500 mg/L) are shown on Figure 29. In summary, based on the TGM VI guidance, the locations where VI is a potential concern at the Site are shown on Figure 36.

For buildings installed in locations where VI is a potential concern, the selected soil vapor remedy will be pathway elimination via the installation of a vapor barrier designed and manufactured for use in VOC mitigation. Alternatively, the results of a VI risk assessment and/or additional soil gas characterization may eliminate the need to install a VI mitigation system in certain areas. To achieve pathway elimination,

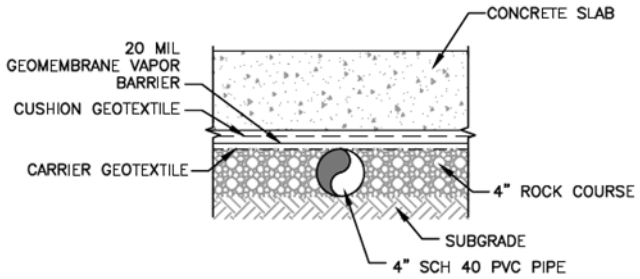
the vapor barrier material will be chemically resistant and have demonstrated low permeability for the VOCs present. Additionally, the EC will prohibit construction of basements in areas of potential VI concern. The selected vapor barrier remedy will:

- Significantly reduce the risk of potential exposure to human receptors in the proposed future building.
- Be accomplished in a reasonable period of time at a reasonable cost.

The two proposed buildings shown in Exhibit 1 (i.e., a 148,611 square-foot building located in the northern portion of the Site and a 740,701 square-foot building located in the central portion of the Site) were evaluated for VI potential. The proposed vapor barrier will be installed beneath both proposed buildings. The vapor barrier proposed for the new buildings is VaporBlock® Plus™ VBP20 Underslab Vapor Retarder/Gas Barrier, as manufactured by Raven Industries, Inc. This is a 20-mil nominal thickness, seven-layer co-extruded barrier constructed using polyethylene and ethylene vinyl alcohol resin. A manufacturer cut sheet for the vapor barrier is provided in Appendix Q. Please note that the attached cut sheet serves as the basis of design for the vapor barrier. However, the manufacturer and final product are subject to change based on market factors. The vapor barrier ultimately used in construction will be an equivalent or better product achieving the specifications in the attached cut sheet. The vapor barrier will be installed and tested in accordance with manufacturer's recommendations.

The vapor barrier will be installed over a carrier geotextile, which in turn, overlies a 4-inch-thick rock course (i.e., gas permeable layer comprised of recycled concrete aggregate/stone subbase in which 4-inch diameter Schedule 40 PVC soil vapor vent piping will be installed to convey sub-slab vapors from beneath the building floor slab to vent riser piping). A cushion geotextile will be installed over the proposed vapor barrier for protection during construction of the concrete floor slab of the proposed building (installation of reinforcement and pouring of concrete). The proposed vapor mitigation components are shown in the cross-section below.

Figure 9-1: Typical Vapor Barrier and Extraction System Cross-Section



While not needed from a vapor risk protection perspective, to be pro-active and conservative, a passive sub-slab ventilation system will be installed beneath both buildings in general accordance with American National Standards Institute's 2018 Standard Soil Gas Control System in New Construction Buildings (ANSI/AARST CC-1000) as an additional protective measure. The passive sub-slab ventilation system will include:

- 4-inch rock course layer (recycled concrete aggregate/stone subbase) to allow for vapor conductance beneath the vapor barrier.

- 4-inch perforated schedule 40 polyvinyl chloride (PVC) horizontal collection piping in the rock course to passively extract soil gas from beneath the vapor barrier and convey the soil gas to 6-inch PVC riser pipes.
- 6-inch PVC riser pipes extending from the horizontal collection piping to convey soil gas collected by the horizontal 4-inch diameter vent piping to an exhaust location at the roof.
- 6-inch wind-driven turbine ventilator at the top of each riser pipe, positioned at least 3-feet above the top of the roof, to increase air flow.

Additional vapor mitigation system details are provided in Exhibit 8.

9.9 Post-Remediation Care Plan

9.9.1 Soil

A PRCP has been developed and is presented as Exhibit 3. In addition, the PRCP will be listed in the environmental covenant because engineering and institutional controls are needed to achieve the site-specific standard. Remedial measures incorporate capping of residual soil impacts. As discussed in Subsection 9.6.1.8, the PRCP specifies the procedures to follow when working in soils underneath the soil cap. Additionally, the following provisions are detailed in the PRCP to assure continued function of the engineering controls:

- Inspecting the engineered caps on a periodic basis. During the first year, the soil cover will be inspected quarterly and after significant rainfall events. Once vegetation is established, the cap will be inspected on an annual basis or as required by any subsequent permit. The visual inspection will include the evaluation of settlement against rigid structures (e.g., buildings, retaining walls, storm structures). If settlement is perceived, a further inspection will be performed which may include intrusive testing (i.e., measuring of total thickness by limited spot excavation) or surveying by a professional surveyor. Additional soil will be added, if needed, to re-establish the 2-foot minimum cap thickness.
- Maintaining the engineered cap and repairing any identified deterioration of the cap units regularly, as encountered. Repairs to the cover system will be made promptly and the corrective action will be documented for inclusion in the Compliance Report. Only certified clean fill as defined by the PADEP Management of Fill Policy will be used to repair the soil cover system.
- Documenting and recording where and when the inspection and maintenance is being conducted.
- Reporting inspection/maintenance results to the PADEP as provided in the environmental covenant (to be developed) in the Periodic Compliance Reports.

Inspection records, documentation associated with any necessary modifications/repairs and copies of notification letters will be maintained by the property owner.

As a component of the Final Report, an environmental covenant will be developed that requires the identification, and long-term inspection and maintenance of those areas where a cap must be maintained.

9.9.2 Groundwater

A site-wide deed restriction prohibiting groundwater use will be incorporated into an Environmental Covenant and recorded with the Philadelphia County Recorder of Deeds.

9.9.3 Vapor Intrusion

The EC will require that a vapor barrier will be installed beneath any inhabited structures constructed onsite and tested and maintained in accordance with the manufacturer's specifications. Alternatively, the requirements for a VI mitigation system beneath a given structure may be eliminated if a VI risk assessment (approved by PADEP) demonstrates that a VI mitigation system is not needed.

9.10 Final Report

Following completion of remediation/redevelopment activities at the Site, an Act 2 Final Report will be prepared for submittal to PADEP. The Final Report will be signed and sealed by a PADEP Professional Geologist or Professional Engineer licensed in Pennsylvania. The report will contain the following:

- A discussion of the remedial activities performed.
- Proof of submissions and notifications of the Final Report.
- All necessary fees.
- Chronological summary of the remediation work performed.
- A list identifying the quantity of materials removed from the Site, and transport bills of lading and/or manifests generated.
- A discussion of any deviations from this Cleanup Plan.
- Relevant permits issued.
- Analytical data generated.
- The Post-Remediation Care Plan.
- Contact information.
- Documentation of the field remedial/redevelopment activities.
- As-built drawings.

Upon approval of the Final Report, an Environmental Covenant that defines the long-term maintenance requirements for any onsite engineering controls and documents the institutional controls requirements that will be needed for remaining soil and groundwater impacts will be recorded.

10 CLEANUP PLAN SUMMARY

The RI was undertaken to assess the nature and extent of Site-related environmental impacts and evaluate the risks posed to human health and the environment by those impacts. The RI results provide adequate data coverage across the Site to: (1) identify and delineate the environmental conditions; (2) support an CSM; (3) develop a cleanup plan; and (4) support Site redevelopment. Based on the RI results, site-related impacts are relatively limited to the center of the Site and at isolated locations on the remainder of the Site.

Currently, there is no complete exposure pathway to impacted soil and groundwater. Future exposure pathways via direct contact with Site soil or groundwater for incidental ingestion, direct dermal contact and/or inhalation of windblown particulates (fugitive dusts) or volatilized COCs will potentially be complete if no controls were to be implemented. Additionally, there is potential for a complete VI exposure pathway when buildings are constructed onsite in the future.

The future exposure pathways can be mitigated via "pathway-elimination" pursuant to an Act 2 Site-Specific Standard. The Site-Specific Standard is a risk management approach. Potentially complete future exposure pathways will be eliminated using engineering and/or institutional controls. Engineering controls proposed for the Site to prevent direct contact exposure include capping impacted soils with asphalt pavement, concrete, building structures and/or clean soil. The Engineering control proposed to prevent potential VI into future buildings on the property includes installing a vapor barrier specifically designed and manufactured for use in VOC mitigation below buildings constructed in areas of potential VI concern unless a VI risk assessment demonstrates that such a control is not needed. Proposed institutional controls include use of deed restriction/environmental covenant prohibiting use of groundwater at the Site. The future exposure pathways and how the proposed remedy eliminates these pathways is summarized in Table 10-1 below.

Table 10-1: Summary of Pathway-Elimination Remedy

Current and/or Future Exposure Pathway	Potential Current Receptors	Potential Future Receptors without Remedy	Proposed Remedy	Potential Future Receptors with Remedy
Incidental Soil and GW Ingestion, Dermal Contact, and Inhalation of VOCs and Particulates	1. Utility/ Construction Worker 2. Outdoor Worker	1. Resident 2. Recreational User 3. Building Occupant 4. Utility/Construction Worker 5. Outdoor Worker 6. Trespasser	• Soil Cap(s) • Institutional Controls	Utility/Construction Workers (i.e., during ground-intrusive activities. Managed in accordance with the PRCP)
Potable Water Ingestion and Use	None	1. Resident 2. Building Occupant 3. Indoor Worker	• GW Use Restrictions	None
Soil Vapor Intrusion	None	1. Resident 2. Building Occupant 3. Indoor Worker	• Vapor Barrier Specific for Site COCs • VI Risk Assessment	None

Note: GW = groundwater

The future use of the property will be restricted to non-residential purposes. The remedial goals for soil will be to allow historic fill and impacted soils to remain in place or be reused onsite underneath a cap (e.g., asphalt/concrete pavement, building structures, a minimum 2-foot thick clean soil cover, etc.), to the extent practicable, and provide cover/capping to the disturbed soil across the Site.

The Cleanup Plan has been developed and details the proposed methods to prevent further migration and eliminate potentially complete exposure pathways.

Notes:

1. The consultant responsible for collecting each sample can be identified by series as follows:
   "PSSTP-" Series in 2003 - Samples were collected by Paulus Sokolowski and Sartor Engineering, PC (PS&S).
   "PC-B" Series in 2005 - Soil borings were advanced by Earth Engineering Incorporated (EEI) and samples were collected by PS&S.
   "PCSB-" Series in 2005 - Samples were collected by PS&S.
   "PCTP-" Series in 2005 - Samples were collected by PS&S.
   "TP-" Series in 2005 - Test pits were excavated by EEI and samples were collected by PS&S.
   "MW-" Series in 2018 and 2019 - Samples were collected by Arcadis U.S., Inc. (Arcadis).
   "S-" Series in 2019 - Samples were collected by Arcadis.
   "..R" Revisited Locations in 2019 - Samples were collected by Arcadis.
2. Sample depth is reported in feet below ground surface.
3. 2003 and 2005 samples were analyzed by Hampton-Clarke, Veritech Laboratories of Fairfield, New Jersey (Veritech).
4. 2018 and 2019 samples were analyzed by SGS North America Incorporated Laboratories of Dayton, New Jersey (SGS).
5. Samples were submitted for laboratory analysis for one or more of the following constituent groups, as indicated above.
   - Target Compound List (TCL) volatile organic compounds (VOC) using United States Environmental Protection Agency (USEPA) SW-846 Method 8260.
   - TCL semi-volatile organic compounds (SVOC) using USEPA SW-846 Method 8270.
   - Metals using USEPA SW-846 Methods 6010 and 7471.
   - Cyanide using USEPA SW-846 Method 9010 (Veritech) or 9012B (SGS).
   - Pesticides using USEPA SW-846 Method 8081.
   - Polychlorinated biphenyls (PCBs) using USEPA SW-846 Method 8082.
6. An **X** indicates analysis was conducted.
7. Saturated indicates that the soil sample is underneath the water table or within the bounds of the capillary fringe area.
8. A soil sample was considered saturated if its elevation was below the higher of either: (1) the groundwater elevation encountered in the soil boring/test pit or (2) the groundwater surface elevation from the highest potentiometric surface map (January 30, 2006 for remedial investigation samples and March 2018 for supplemental samples).
9. NA = Saturation could not be determine because the parent sample for this duplicate sample is not available.
10. Revisited sampling locations were renamed with the suffix "R", and represent the same location as the historical sampling locations without the suffix "R".

Notes:

1. Samples from 2005 and 2006 were collected by Paulus Sokolowski and Sartor Engineering, PC. Samples from 2018 and 2019 were collected by Arcadis U.S., Inc.
2. 2005 and 2006 samples were analyzed by Hampton-Clarke, Veritech Laboratories of Fairfield, New Jersey (Veritech).
3. 2018 and 2019 samples were analyzed by SGS North America Incorporated Laboratories of Dayton, New Jersey (SGS), except free cyanide samples which were analyzed by TestAmerica of Amherst, New York.
4. Samples were submitted for laboratory analysis for one or more of the following constituent groups, as indicated above.
   - Target Compound List (TCL) volatile organic compounds (VOC) using United States Environmental Protection Agency (USEPA) SW-846 Method 8260.
   - TCL semi-volatile organic compounds (SVOC) using USEPA SW-846 Method 8270.
   - Metals using USEPA SW-846 Methods 200.7 (Veritech), 245.1 (Veritech), 6010 (SGS), and 7470 (SGS). Dissolved metals were analyzed using the same methodology but were filtered prior to analysis.
   - Total cyanide using USEPA Method 335.1 (Veritech) or 335.4 (SGS).
   - Free cyanide using USEPA SW-846 Method 9016.
   - Total dissolved solids using American Society for Testing and Materials Method SM2540 C-11.
   - Pesticides using USEPA SW-846 Method 8081.
   - Polychlorinated biphenyls (PCBs) using USEPA SW-846 Method 8082.
5. An **X** indicates analysis was conducted.
6. * indicates that the groundwater monitoring well was installed to replace the missing historical well also listed in the monitoring well ID.

Notes:

1. Table presents sample intervals where visual impacts and coal tar-like odors were observed. Table also presents the sample intervals with photoionization detector (PID) headspace readings above 0.0 parts per million (ppm) and sample intervals analyzed for polycyclic aromatic hydrocarbons (PAHs). Even if there are no visual impacts, soil samples analyzed for PAHs, or elevated PID readings, 2018 and 2019 soil borings and test pits are summarized within to document the observed saturation depth and silty-clay layer contact depth.
2. The consultant responsible for performing soil borings and test pits can be identified by series as follows:
   "W-" Series in 1985 and 1986 - Monitoring wells were installed and logged by Woodward-Clyde Consultants (WCC).
   "B-" Series in 1986 - Soil borings advanced and logged by WCC.
   "PSSTP-" Series in 2003 - Test pits excavated and logged by Paulus Sokolowski and Sartor Engineering, PC (PS&S).
   "PC-B" Series in 2005 - Soil borings were advanced by Earth Engineering Incorporated (EEI) and logged by PS&S.
   "PCSB-" Series in 2005 - Soil borings were advanced and logged by PS&S.
   "PCTP-" Series in 2005 - Test pits were excavated and logged by PS&S.
   "TP-" Series in 2005 - Test pits were excavated by EEI and logged by PS&S.
   "MW-" Series in 2018 and 2019 - Monitoring wells were installed and logged by Arcadis U.S., Inc. (Arcadis).
   "S-" Series in 2019 - Soil borings and test pits were performed by Arcadis.
   "..R" Revisited Locations in 2019 - Soil borings and test pits were performed by Arcadis.
3. Depths are measured in feet below ground surface (ft bgs).
4. Gray shading and black borders indicate that the test pit or soil boring was performed in 2018 or 2019.
5. PID headspace screening results are reported in ppm.
6. If the presented sample interval had more than three PID readings, the range of PID readings is presented from minimum to maximum for that interval.
7. Total PAH is the sum of the 16 priority pollutant PAHs identified by the United States Environmental Protection Agency (USEPA) and 2-methylnaphthalene.
8. Duplicate values are presented in brackets [ ].
9. SB = Soil boring.
10. TP = Test pit.
11. HA = Hand auger.
12. N/A = Not available.
13. NA = Not analyzed for PAHs.
14. -- = Not encountered.
15. Revisited sampling locations were renamed with the suffix "R", and represent the same location as the historical sampling locations without the suffix "R".
16. Site locations are further described below:
    Area 1A = Eastern part of former coal storage area (around PCTP-75R).
    Area 1B = East of former coal storage area (around PSSTP-04R).
    Area 2 = North/Northwest of former tar storage area.
    Area 3A = South of former tar storage area (around TP-15).
    Area 3B = South of former tar storage area (around PCTP-66).
    Area 4 = East of former byproducts building.
    Central Site = General region between Areas 1, 2, and 3.
    FBA = Fuel blending area.
    FBA: Perimeter = Perimeter location within the fuel blending area.
    FBA: RR = Fuel blending area: near inactive railroad track (around PCSB-41R).
    Northern Corner = Northern corner of the Site near intersection of Buckius and Richmond Streets (around PCSB-01R).
    Perimeter = Perimeter location outside of the fuel blending area.
    RCRA Area = 1990's Resource Conservation and Recovery Act soil removal area.
    Misc. = Sample location that is outside the above mentioned areas.

Notes:

1. NAVD 88 = North American Vertical Datum of 1988.
2. ags = above gound surface.
3. bgs = below gound surface.
4. Monitoring wells were completed with steel stick-up protective casings.
5. Monitoring wells were constructed with polyvinyl chloride inner casings.
6. Monitoring wells were not installed with a sump (i.e., well depths are equal to screen depths), except MW-111 which has a 1-foot sump underneath the screened interval and MW-5 which has a 2-foot sump underneath the screened interval.
7. Each deep well (well ID contains suffix D) has a steel casing extending through the fill layer.
8. The following wells are destroyed or could not be found during any of the 2018 groundwater sampling events:
   - PCMW-02
   - PCMW-03
   - PCMW-09D
   - PCMW-11D
   - PCMW-12D
   - PCMW-13D
   - PCMW-13S
   - PCMW-14D
   - PCMW-14S
   - PCMW-16S
9. The screen intervals for both MW-5 and MW-6 were estimated based on the downhole camera footage.

Table 5
Groundwater Elevation Data

Remedial Investigation Report
National Grid Former Philadelphia Coke Plant
Philadelphia, Pennsylvania

Notes:

1. Gray shading indicates that the elevations is referenced to feel above mean sea level. For these locations, the vertical datum is unknown because the wells were not resurveyed during the supplemental investigation. The reference point elevation used for these wells is the elevation reporting during the initial investigation, and the vertical datum was not indicated in the initial investigatior
2. NAVD 88 = North American Vertical Datum of 1988.
3. MW = monitoring well.
4. bmp = below measuring point.
5. MISSING/DESTROYED = monitoring well was unable to be found, destroyed, or inaccessible.
6. Obstructed = monitoring well was obstructed
7. DRY = monitoring well was void of water except on the surface of the base of the well.
8. -- = Not applicable. Well wasn't installed.
9. NM = Not measured.

Notes:

1. Northing and Eastings are in feet referenced to the North American Datum of 1983, State Plane of Pennsylvania-South.
2. Elevations are in feet referenced to the North American Vertical Datum of 1988.
3. Revisited sampling locations were renamed with the suffix "R", and represent the same location as the historical sampling locations without the suffix "R".
4. Reported monitoring well, soil boring, and test pit elevations are the ground surface. Reported subsurface utility elevations are the top of pipe, except for MH-4 where the reported elevation is the ground surface.

Table 7
Surface Soil Analytical Results – Detected VOCs, SVOCs, and Inorganics (mg/kg)

Remedial Investigation Report
National Grid Former Philadelphia Coke Plant
Philadelphia, Pennsylvania

Notes:

1. Samples prior to 2019 were collected by Paulus, Sokolowski, and Sartor Engineering, PC on the dates indicated. Samples in 2019 were collected by Arcadis on the dates indicated.
2. Sample depth is reported in feet below ground surface.
3. 2003 and 2005 samples were analyzed by Hampton-Clarke, Veritech Laboratories of Fairfield, New Jersey (Veritech).
4. 2019 samples were analyzed by SGS North America Incorporated Laboratories of Dayton, New Jersey (SGS).
5. Samples were submitted for laboratory analysis for one or more of the following constituent groups, as indicated above.
   - Target Compound List (TCL) volatile organic compounds (VOC) using United States Environmental Protection Agency (USEPA) SW-846 Method 8260.
   - TCL semi-volatile organic compounds (SVOC) using USEPA SW-846 Method 8270.
   - Metals using USEPA SW-846 Methods 6010 and 7471.
   - Cyanide using USEPA SW-846 Method 9010 (Veritech) or 9012B (SGS).
6. Only compounds detected in one or more samples are shown in this table.
7. < = constituent not detected at a concentration above the reported detection limit. These results are also reported in gray.
8. NA = Not Analyzed.
9. Concentrations reported in milligrams per kilogram (mg/kg) or parts per million (ppm).
10. Soil standards obtained from the Pennsylvania Department of Environmental Protection (PADEP) Medium Specific Concentrations (MSCs) established in Title 25 of the Pennsylvania Code Chapter 250, Administration of the Land Recycling Program (Act 2 cleanup standards) updated on November 20, 2021, and include:
    (a) The soil to groundwater MSCs for a non-residential used aquifer with total dissolved solids (TDS) less than or equal to 2,500 parts per million (ppm). The higher of the 100 X groundwater MSC or generic value is used.
    (b) The non-residential direct contact MSC for surface soil.
11. Shading indicates that the result exceeds the PADEP non-residential direct contact MSC (for surface soil).
12. Italics and bolding indicates that the result exceeds the PADEP soil to groundwater MSC (for a non-residential used aquifer with TDS ≤ 2,500 ppm).
13. - - = No PADEP MSC.
14. - = No actual Chemical Abstracts Service (CAS) number is available.
15. Brackets indicate the reported concentration of a duplicate sample.
16. The MSCs reported for chromium is for trivalent chromium. The reported chromium results are for total chromium.
17. The MSCs reported for cyanide are for free cyanide. The reported cyanide results are for total cyanide.
18. Total polycyclic aromatic hydrocarbons (PAHs) are the sum of the 16 priority pollutant PAHs identified by the USEPA and 2-methylnaphthalene.
19. Qualifier Definitions:
    B = Analyte is an estimated value between the instrument detection limit and the Reporting Limit.
    D = Concentration is based on a diluted sample analysis.
    J = Analyte is an estimated value.
    R = Data rejected during validation.
20. Data from 2019 have undergone a Tier II validation. Data prior to 2019 have not been validated.

Notes:

1. Samples prior to 2019 were collected by Paulus, Sokolowski, and Sartor Engineering, PC on the dates indicated. Samples in 2019 were collected by Arcadis on the dates indicated.
2. Sample depth is reported in feet below ground surface.
3. 2003 and 2005 samples were analyzed by Hampton-Clarke, Veritech Laboratories of Fairfield, New Jersey.
4. 2019 samples were analyzed by SGS North America Incorporated Laboratories of Dayton, New Jersey.
5. Samples were submitted for laboratory analysis for one or more of the following constituent groups, as indicated above.
   - Pesticides using United States Environmental Protection Agency (USEPA) SW-846 Method 8081.
   - Polychlorinated biphenyls (PCBs) using USEPA SW-846 Method 8082.
6. Only compounds detected in one or more samples are shown in this table.
7. < = constituent not detected at a concentration above the reported detection limit. These results are also reported in gray.
8. NA = Not Analyzed.
9. Concentrations reported in milligrams per kilogram (mg/kg) or parts per million (ppm).
10. Soil standards obtained from the Pennsylvania Department of Environmental Protection (PADEP) Medium Specific Concentrations (MSCs) established in Title 25 of the Pennsylvania Code Chapter 250, Administration of the Land Recycling Program (Act 2 cleanup standards) updated on November 20, 2021, and include:
    (a) The soil to groundwater MSCs for a non-residential used aquifer with total dissolved solids (TDS) less than or equal to 2,500 parts per million (ppm). The higher of the 100 X groundwater MSC or generic value is used.
    (b) The non-residential direct contact MSC for surface soil.
11. No results exceed the PADEP non-residential direct contact MSC (for surface soil) or the PADEP soil to groundwater MSC (for a non-residential used aquifer with TDS ≤ 2,500 ppm).
12. - - = No PADEP MSC.
13. - = No actual Chemical Abstracts Service (CAS) number is available.
14. Brackets indicate the reported concentration of a duplicate sample.
15. Qualifier Definitions:
    E = Serial dilution results not within 10%. Applicable only if analyte concentration is at least 50X the IDL in original sample.
    HD = Unknown. Potential ND mistranscribed. Laboratory analytical report not available.
    J = Analyte is an estimated value.
    N = There is presumptive evidence to make a tentative identification of this compound.
16. Data from 2019 have undergone a Tier II validation. Data prior to 2019 have not been validated.

Table 9
Unsaturated Soil Analytical Results – Detected VOCs, SVOCs, and Inorganics (mg/kg)

Notes:

1. Samples prior to 2018 were collected by Paulus, Sokolowski, and Sartor Engineering, PC on the dates indicated. Samples in 2018 and 2019 were collected by Arcadis on the dates indicated.
2. Sample depth is reported in feet below ground surface.
3. 2003 and 2005 samples were analyzed by Hampton-Clarke, Veritech Laboratories of Fairfield, New Jersey (Veritech).
4. 2018 and 2019 samples were analyzed by SGS North America Incorporated Laboratories of Dayton, New Jersey (SGS).
5. Samples were submitted for laboratory analysis for one or more of the following constituent groups, as indicated above.
   - Target Compound List (TCL) volatile organic compounds (VOC) using United States Environmental Protection Agency (USEPA) SW-846 Method 8260.
   - TCL semi-volatile organic compounds (SVOC) using USEPA SW-846 Method 8270.
   - Metals using USEPA SW-846 Methods 6010 and 7471.
   - Cyanide using USEPA SW-846 Method 9010 (Veritech) or 9012B (SGS).
6. Only compounds detected in one or more samples are shown in this table.
7. < = constituent not detected at a concentration above the reported detection limit. These results are also reported in gray.
8. NA = Not Analyzed.
9. Concentrations reported in milligrams per kilogram (mg/kg) or parts per million (ppm).
10. Soil standards obtained from the Pennsylvania Department of Environmental Protection (PADEP) Medium Specific Concentrations (MSCs) established in Title 25 of Chapter 250, Administration of the Land Recycling Program (Act 2 cleanup standards) updated on November 20, 2021, and include:
    (a) The soil to groundwater MSCs for a non-residential used aquifer with total dissolved solids (TDS) less than or equal to 2,500 parts per million (ppm). The higher of the 100 X groundwater MSC or generic value is used.
    (b) The non-residential direct contact MSC for subsurface soil.
11. Shaded results indicates that the result exceed the PADEP non-residential direct contact MSC (for subsurface soil).
12. Italics and bolding indicates that the result exceeds the PADEP soil to groundwater MSC (for a non-residential used aquifer with TDS ≤ 2,500 ppm).
13. - - = No PADEP MSC.
14. - = No actual Chemical Abstracts Service (CAS) number is available.
15. Brackets indicate the reported concentration of a duplicate sample.
16. The MSCs reported for chromium is for trivalent chromium. The reported chromium results are for total chromium.
17. The MSCs reported for cyanide are for free cyanide. The reported cyanide results are for total cyanide.
18. Total polycyclic aromatic hydrocarbons (PAHs) are the sum of the 16 priority pollutant PAHs identified by the USEPA and 2-methylnaphthalene.
19. Qualifier Definitions:
    B = Analyte is an estimated value between the instrument detection limit and the Reporting Limit.
    D = Concentration is based on a diluted sample analysis.
    J = Analyte is an estimated value.
    R = Data rejected during validation.
20. Data from 2018 and 2019 have undergone a Tier II validation. Data prior to 2018 have not been validated.

Notes:

1. Samples prior to 2018 were collected by Paulus, Sokolowski, and Sartor Engineering, PC on the dates indicated. Samples in 2018 and 2019 were collected by Arcadis on the dates indicated.
2. Sample depth is reported in feet below ground surface.
3. 2003 and 2005 samples were analyzed by Hampton-Clarke, Veritech Laboratories of Fairfield, New Jersey.
4. 2018 and 2019 samples were analyzed by SGS North America Incorporated Laboratories of Dayton, New Jersey.
5. Samples were submitted for laboratory analysis for one or more of the following constituent groups, as indicated above.
   - Pesticides using United States Environmental Protection Agency (USEPA) SW-846 Method 8081.
   - Polychlorinated biphenyls (PCBs) using USEPA SW-846 Method 8082.
6. Only compounds detected in one or more samples are shown in this table.
7. < = constituent not detected at a concentration above the reported detection limit. These results are also reported in gray.
8. NA = Not Analyzed.
9. Concentrations reported in milligrams per kilogram (mg/kg) or parts per million (ppm).
10. Soil standards obtained from the Pennsylvania Department of Environmental Protection (PADEP) Medium Specific Concentrations (MSCs) established in Title 25 of the Chapter 250, Administration of the Land Recycling Program (Act 2 cleanup standards) updated on November 20, 2021, and include:
    (a) The soil to groundwater MSCs for a non-residential used aquifer with total dissolved solids (TDS) less than or equal to 2,500 parts per million (ppm). The higher of the 100 X groundwater MSC or generic value is used.
    (b) The non-residential direct contact MSC for subsurface soil.
11. No results exceed the PADEP non-residential direct contact MSC (for subsurface soil) or the PADEP soil to groundwater MSC (for a non-residential used aquifer with TDS ≤ 2,500 ppm).
12. - - = No PADEP MSC.
13. - = No actual Chemical Abstracts Service (CAS) number is available.
14. Brackets indicate the reported concentration of a duplicate sample.
15. Qualifier Definitions:
    J = Analyte is an estimated value.
    N = There is presumptive evidence to make a tentative identification of this compound.
16. Data from 2018 and 2019 have undergone a Tier II validation. Data prior to 2018 have not been validated.

Table 11
Saturated Soil Analytical Results – Detected VOCs, SVOCs, and Inorganics (mg/kg)

Remedial Investigation Report
National Grid Former Philadelphia Coke Plant
Philadelphia, Pennsylvania

Notes:

1. Samples prior to 2018 were collected by Paulus, Sokolowski, and Sartor Engineering, PC on the dates indicated. Samples in 2018 and 2019 were collected by Arcadis on the dates indicated.
2. Sample depth is reported in feet below ground surface.
3. 2003 and 2005 samples were analyzed by Hampton-Clarke, Veritech Laboratories of Fairfield, New Jersey (Veritech).
4. 2018 and 2019 samples were analyzed by SGS North America Incorporated Laboratories of Dayton, New Jersey (SGS).
5. Samples were submitted for laboratory analysis for one or more of the following constituent groups, as indicated above.
   - Target Compound List (TCL) volatile organic compounds (VOC) using United States Environmental Protection Agency (USEPA) SW-846 Method 8260.
   - TCL semi-volatile organic compounds (SVOC) using USEPA SW-846 Method 8270.
   - Metals using USEPA SW-846 Methods 6010 and 7471.
   - Cyanide using USEPA SW-846 Method 9010 (Veritech) or 9012B (SGS).
6. Only compounds detected in one or more samples are shown in this table.
7. < = constituent not detected at a concentration above the reported detection limit. These results are also reported in gray.
8. NA = Not Analyzed.
9. Concentrations reported in milligrams per kilogram (mg/kg) or parts per million (ppm).
10. Soil standards obtained from the Pennsylvania Department of Environmental Protection (PADEP) Medium Specific Concentrations (MSCs) established in Title 25 of the Pennsylvania Code Chapter 250, Administration of the Land Recycling Program (Act 2 cleanup standards) updated on November 20, 2021 and include:
    (a) The soil to groundwater MSCs for a non-residential used aquifer with total dissolved solids (TDS) less than or equal to 2,500 parts per million (ppm). The higher of the 100 X groundwater MSC or generic value is used.
    (b) The non-residential direct contact MSC for subsurface soil.
11. Shaded results indicates that the results exceed the PADEP non-residential direct contact MSC (for subsurface soil).
12. Italics and bolding indicates that the result exceeds the PADEP soil to groundwater MSC (for a non-residential used aquifer with TDS ≤ 2,500 ppm).
13. - - = No PADEP MSC.
14. - = No actual Chemical Abstracts Service (CAS) number is available.
15. Brackets indicate the reported concentration of a duplicate sample.
16. The MSCs reported for chromium is for trivalent chromium. The reported chromium results are for total chromium.
17. The MSCs reported for cyanide are for free cyanide. The reported cyanide results are for total cyanide.
18. Total polycyclic aromatic hydrocarbons (PAHs) are the sum of the 16 priority pollutant PAHs identified by the USEPA and 2-methylnaphthalene.
19. Qualifier Definitions:
    B = Analyte is an estimated value between the instrument detection limit and the Reporting Limit.
    D = Concentration is based on a diluted sample analysis.
    J = Analyte is an estimated value.
    R = Data rejected during validation.
20. Data from 2018 and 2019 have undergone a Tier II validation. Data prior to 2018 have not been validated.

Notes:

1. Samples prior to 2018 were collected by Paulus, Sokolowski, and Sartor Engineering, PC on the dates indicated. Samples in 2018 and 2019 were collected by Arcadis on the dates indicated.
2. Sample depth is reported in feet below ground surface.
3. 2003 and 2005 samples were analyzed by Hampton-Clarke, Veritech Laboratories of Fairfield, New Jersey.
4. 2018 and 2019 samples were analyzed by SGS North America Incorporated Laboratories of Dayton, New Jersey.
5. Samples were submitted for laboratory analysis for one or more of the following constituent groups, as indicated above.
   - Pesticides using United States Environmental Protection Agency (USEPA) SW-846 Method 8081.
   - Polychlorinated biphenyls (PCBs) using USEPA SW-846 Method 8082.
6. Only compounds detected in one or more samples are shown in this table.
7. < = constituent not detected at a concentration above the reported detection limit. These results are also reported in gray.
8. NA = Not Analyzed.
9. Concentrations reported in milligrams per kilogram (mg/kg) or parts per million (ppm).
10. Soil standards obtained from the Pennsylvania Department of Environmental Protection (PADEP) Chapter 250, Administration of the Land Recycling Program (Act 2 cleanup standards) updated on November 20, 2021, and include:
    (a) The soil to groundwater MSCs for a non-residential used aquifer with total dissolved solids (TDS) less than or equal to 2,500 parts per million (ppm). The higher of the 100 X groundwater MSC or generic value is used.
    (b) The non-residential direct contact MSC for subsurface soil.
11. No results exceed the PADEP non-residential direct contact MSC (for subsurface soil) or the PADEP soil to groundwater MSC (for a non-residential used aquifer with TDS ≤ 2,500 ppm).
12. - - = No PADEP MSC.
13. - = No actual Chemical Abstracts Service (CAS) number is available.
14. Qualifier Definitions:
    J = Analyte is an estimated value.
    N = There is presumptive evidence to make a tentative identification of this compound.
15. Data from 2018 and 2019 have undergone a Tier II validation. Data prior to 2018 have not been validated.

Notes:

1. Samples were submitted for laboratory analysis for one or more of the following constituent groups, as indicated above.
   - Target Compound List (TCL) volatile organic compounds (VOC) using United States Environmental Protection Agency (USEPA) SW-846 Method 8260.
   - TCL semi-volatile organic compounds (SVOC) using USEPA SW-846 Method 8270.
   - Metals using USEPA SW-846 Methods 6010 and 7471.
   - Cyanide using USEPA SW-846 Method 9010 or 9012B.
   - Pesticides using USEPA SW-846 Method 8081.
   - Polychlorinated biphenyls (PCBs) using USEPA SW-846 Method 8082.
2. Only compounds detected in one or more samples are shown in this table.
3. Analytes detected in sample are shown in black font and analytes that are not detected are shown in gray font.
4. For purposes of this statistical analysis, field duplicate results are averaged with their parent sample and the average is counted as one sample. If the resulting average is a minimum or maximum concentration, it is reported as such. If either the parent or duplicate result is non-detect while the other is detected, only the detected concentration is used. If either the parent or the duplicate exceed an MCS, it is reported as such.
5. Concentrations reported in milligrams per kilogram (mg/kg) or parts per million (ppm).
6. Soil standards obtained from the Pennsylvania Department of Environmental Protection (PADEP) Medium Chapter 250, Administration of the Land Recycling Program (Act 2 cleanup standards) updated on November 20, 2021, and include:
   (a) The soil to groundwater MSCs for a non-residential used aquifer with total dissolved solids (TDS) less than or equal to 2,500 parts per million (ppm). The higher of the 100 X groundwater MSC or generic value is used.
   (b) The non-residential direct contact MSC for surface and subsurface soil.
7. Gray shading indicates that the result exceed the PADEP non-residential direct contact MSC (for subsurface soil).
8. Orange shading indicates that the result exceeds the PADEP non-residential direct contact MSC (for surface soil).
9. Italics and bolding indicates that the result exceeds the PADEP soil to groundwater MSC (for a non-residential used aquifer with TDS ≤ 2,500 ppm).
10. - - = No PADEP MSC.
11. - = No actual Chemical Abstracts Service (CAS) number is available.
12. ND = Not detected.
13. The MSCs reported for chromium is for trivalent chromium. The reported chromium results are for total chromium.
14. The MSCs reported for cyanide are for free cyanide. The reported cyanide results are for total cyanide.
15. Rejected data was not counted for total number of samples collected.
16. Total polycyclic aromatic hydrocarbons (PAHs) are the sum of the 16 priority pollutant PAHs identified by the USEPA and 2-methylnaphthalene.
17. Data qualifiers are not presented in this table.
18. Data from 2018 and 2019 have undergone a Tier II validation. Data prior to 2018 have not been validated.

Notes:
1. Samples were collected by Paulus, Sokolowski, and Sartor Engineering, PC on the dates indicated.
2. Samples were analyzed by Hampton-Clarke, Veritech Laboratories of Fairfield, New Jersey for the following:
   - Target Compound List (TCL) volatile organic compounds (VOC) using United States Environmental Protection Agency (USEPA) SW-846 Method 8260.
   - TCL semi-volatile organic compounds (SVOC) using USEPA SW-846 Method 8270.
   - Metals using USEPA SW-846 Methods 200.7 and 245.1.
3. Only compounds detected in one or more samples are shown in this table.
4. < = constituent not detected at a concentration above the reported detection limit. These results are also reported in gray.
5. Concentrations reported in micrograms per liter (ug/L) or parts per billion (ppb).
6. Shading indicates an exceedance of Pennsylvania Department of Environmental Protection's (PADEP's) non-residential Medium Specific Concentrations (MSCs) for Used Aquifers containing Total Dissolved Solids (TDS) ≤ 2,500 milligrams per liter (mg/L).
7. Italics and bolding indicates an exceedance of PADEP's Residential MSCs for Used Aquifers containing TDS ≤ 2,500 mg/L.
8. - - = No PADEP Groundwater Standard.
9. The groundwater standards reported for cyanide are for free cyanide. The reported cyanide results are for amenable cyanide.
10. Data have not been validated.

Notes:

1. Samples prior to 2018 were collected by Paulus, Sokolowski, and Sartor Engineering, PC on the dates indicated. Samples in 2018 and 2019 were collected by Arcadis on the dates indicated.
2. 2005 and 2006 samples were analyzed by Hampton-Clarke, Veritech Laboratories of Fairfield, New Jersey.
3. 2018 and 2019 samples were analyzed by SGS North America Incorporated Laboratories of Dayton, New Jersey.
4. Samples were submitted for laboratory analysis for one or more of the following constituent groups, as indicated above.
   - Target Compound List (TCL) volatile organic compounds (VOC) using United States Environmental Protection Agency (USEPA) SW-846 Method 8260D.
   - TCL semi-volatile organic compounds (SVOC) using USEPA SW-846 Method 8270.
   - Pesticides using USEPA SW-846 Method 8081.
   - Polychlorinated biphenyls (PCBs) using USEPA SW-846 Method 8082.
5. Only compounds detected in one or more samples are shown in this table.
6. < = constituent not detected at a concentration above the reported detection limit. These results are also reported in gray.
7. NA = Not Analyzed.
8. Concentrations reported in micrograms per liter (ug/L) or parts per billion (ppb).
9. Shading indicates an exceedance of Pennsylvania Department of Environmental Protection's (PADEP's) non-residential Medium Specific Concentrations (MSCs) for Used Aquifers containing Total Dissolved Solids (TDS) ≤ 2,500 milligrams per liter (mg/L).
10. Italics and bolding indicates an exceedance of PADEP's Residential MSCs for Used Aquifers containing TDS ≤ 2,500 mg/L.
11. - - = No PADEP MSC.
12. - = No actual Chemical Abstracts Service (CAS) number is available.
13. * indicates that the groundwater monitoring well was installed to replace the missing historical well also listed in the monitoring well ID.
14. Brackets indicate the reported concentration of a duplicate sample.
15. Qualifier Definitions:
    B = The compound has been found in the sample as well as its associated blank.
    D = Concentration is based on a diluted sample analysis.
    J = Analyte is an estimated value.
16. Data from 2018 and 2019 have undergone a Tier II validation. Data prior to 2018 have not been validated.

Notes:

1. Samples prior to 2018 were collected by Paulus, Sokolowski, and Sartor Engineering, PC on the dates indicated. Samples in 2018 and 2019 were collected by Arcadis on the dates indicated.
2. 2005 and 2006 samples were analyzed by Hampton-Clarke, Veritech Laboratories of Fairfield, New Jersey (Veritech).
3. 2018 and 2019 samples were analyzed by SGS North America Incorporated Laboratories of Dayton, New Jersey (SGS).
4. Samples were submitted for laboratory analysis for one or more of the following constituent groups, as indicated above.
   - Total dissolved solids using American Society for Testing and Materials Method SM2540 C-11.
   - Metals using United States Environmental Protection Agency (USEPA) SW-846 Methods 200.7 (Veritech), 245.1 (Veritech), 6010 (SGS), and 7470 (SGS).
   - Total cyanide using USEPA Method 335.1 (Veritech) or 335.4 (SGS).
5. Only compounds detected in one or more samples are shown in this table.
6. < = constituent not detected at a concentration above the reported detection limit. These results are also reported in gray.
7. NA = Not Analyzed.
8. Concentrations reported in micrograms per liter (ug/L) or parts per billion (ppb).
9. Shading indicates an exceedance of Pennsylvania Department of Environmental Protection's (PADEP's) non-residential Medium Specific Concentrations (MSCs) for Used Aquifers containing Total Dissolved Solids (TDS) ≤ 2,500 milligrams per liter (mg/L).
10. Italics and bolding indicates an exceedance of PADEP's Residential MSCs for Used Aquifers containing TDS ≤ 2,500 mg/L.
11. - - = No PADEP MSC.
12. * indicates that the groundwater monitoring well was installed to replace the missing historical well also listed in the monitoring well ID.
13. The groundwater standards reported for cyanide are for free cyanide. The reported groundwater results are for total cyanide.
14. Brackets indicate the reported concentration of a duplicate sample.
15. Qualifier Definition:
    J = Analyte is an estimated value.
16. Data from 2018 and 2019 have undergone a Tier II validation. Data prior to 2018 have not been validated.

Table 17
Groundwater Analytical Results – Detected Dissolved Inorganics & Free Cyanide (mg/L)

Remedial Investigation Report
National Grid Former Philadelphia Coke Plant
Philadelphia, Pennsylvania

Notes:
1. Samples prior to 2018 were collected by Paulus, Sokolowski, and Sartor Engineering, PC on the dates indicated. Samples in 2018 and 2019 were collected by Arcadis on the dates indicated.
2. 2005 and 2006 samples were analyzed by Hampton-Clarke, Veritech Laboratories of Fairfield, New Jersey (Veritech).
3. 2018 and 2019 samples were analyzed by SGS North America Incorporated Laboratories of Dayton, New Jersey (SGS), except free cyanide samples which were analyzed by TestAmerica of Amherst, New York.
4. Samples were submitted for laboratory analysis for one or more of the following constituent groups, as indicated above.
   - Dissolved metals using United States Environmental Protection Agency (USEPA) SW-846 Methods 200.7 (Veritech), 245.1 (Veritech), 6010 (SGS), and 7470 (SGS).
   - Free cyanide using USEPA Method 9016.
5. Only compounds detected in one or more samples are shown in this table.
6. < = constituent not detected at a concentration above the reported detection limit. These results are also reported in gray.
7. NA = Not Analyzed.
8. Concentrations reported in micrograms per liter (ug/L) or parts per billion (ppb).
9. Shading indicates an exceedance of Pennsylvania Department of Environmental Protection's (PADEP's) non-residential Medium Specific Concentrations (MSCs) for Used Aquifers containing Total Dissolved Solids (TDS) ≤ 2,500 milligrams per liter (mg/L).
10. Italics and bolding indicates an exceedance of PADEP's Residential MSCs for Used Aquifers containing TDS ≤ 2,500 mg/L.
11. - - = No PADEP MSC.
12. Brackets indicate the reported concentration of a duplicate sample.
13. Qualifier Definition:
    J = Analyte is an estimated value.
14. Data from 2018 and 2019 have undergone a Tier II validation. Data prior to 2018 have not been validated.

Table 18
Groundwater Analytical Statistics for Detected Compounds

Remedial Investigation Report
National Grid Former Philadelphia Coke Plant
Philadelphia, Pennsylvania

Notes:

1. Samples were submitted for laboratory analysis for one or more of the following constituent groups, as indicated above.
   - Target Compound List (TCL) volatile organic compounds (VOC) using United States Environmental Protection Agency (USEPA) SW-846 Method 8260.
   - TCL semi-volatile organic compounds (SVOC) using USEPA SW-846 Method 8270.
   - Pesticides using USEPA SW-846 Method 8081.
   - Polychlorinated biphenyls (PCBs) using USEPA SW-846 Method 8082.
   - Metals using USEPA SW-846 Methods 200.7, 245.1, 6010, and 7470. Dissolved metals were analyzed using the same methodology but were filtered prior to analysis.
   - Total cyanide using USEPA Method 335.1 or 335.4.
   - Free cyanide using USEPA SW-846 Method 9016.
   - Total dissolved solids using American Society for Testing and Materials Method SM2540 C-11.
2. Only compounds detected in one or more samples are shown in this table.
3. For purposes of this statistical analysis, field duplicate results are averaged with their parent sample and the average is counted as one sample. If the resulting average is a minimum or maximum concentration, it is reported as such. If either the parent or duplicate result is non-detect while the other is detected, only the detected concentration is used.
4. Concentrations reported in micrograms per liter (ug/L) or parts per billion (ppb).
5. Shading indicates an exceedance of Pennsylvania Department of Environmental Protection's (PADEP's) non-residential Medium Specific Concentrations (MSCs) for Used Aquifers containing Total Dissolved Solids (TDS) ≤ 2,500 milligrams per liter (mg/L).
6. Italics and bolding indicates an exceedance of PADEP's Residential MSCs for Used Aquifers containing TDS ≤ 2,500 mg/L.
7. - - = No PADEP MSC.
8. ND = Not detected.
9. The groundwater standards reported for cyanide are for free cyanide.
10. Hydropunch results have not been included in this table.
11. Data qualifiers are not presented in this table.
12. Data from 2018 and 2019 have undergone a Tier II validation. Data prior to 2018 have not been validated.

Table 19
Historical Soil Vapor Sampling Results for Detected Constituents

Remedial Investigation Report
National Grid Former Philadelphia Coke Plant
Philadelphia, Pennsylvania

Notes:

1. Samples were collected by Paulus, Sokolowski, and Sartor Engineering, PC on the dates indicated.
2. Soil samples were analyzed by Air Toxics LTD, located in Folsom, California for the following:
   - Volatile organic compounds and naphthalene using the Modified EPA Compendium Method TO-15 and GC/MS in the full scan mode.
   - Methane and fixed gases using modified ASTM Method D-1946 and GC/FID or GC/TCD.
3. Only compounds detected in one or more samples are shown in this table.
4. < = constituent not detected at a concentration above the reported detection limit. These results are also reported in gray.
5. Concentrations reported in micrograms per cubic meter (ug/m^3) or part per billion by volume (ppbv).
6. Soil vapor screening values for residential and non-residential, sub-slab, soil gas (SV_{SS}) obtained from the Pennsylvania Department of Environmental Protection (PADEP) Land Recycling Program Technical Guidance Manual for Vapor Intrusion into Buildings from Groundwater and Soil under Act 2, published on November 19, 2016 and effective January 18, 2017.
7. No result exceed the non-residential SV_{SS} screening value.
8. Italics and bolding indicates that the result exceeds the residential SVSS screening value.
9. Brackets indicate the reported concentration of a duplicate sample.
10. - - = No soil vapor screening value.
11. Data have not been validated.

Notes:

1. Samples prior to 2019 were collected by Paulus, Sokolowski, and Sartor Engineering, PC on the dates indicated. Samples in 2019 were collected by Arcadis on the dates indicated.
2. Sample depth is reported in feet below ground surface.
3. 2003 and 2005 samples were analyzed by Hampton-Clarke, Veritech Laboratories of Fairfield, New Jersey.
4. 2019 samples were analyzed by SGS North America Incorporated Laboratories of Dayton, New Jersey.
5. Samples were submitted for laboratory analysis for one or more of the following constituent groups, as indicated above.
   - Target Compound List (TCL) volatile organic compounds (VOC) using United States Environmental Protection Agency (USEPA) SW-846 Method 8260.
   - TCL semi-volatile organic compounds (SVOC) using USEPA SW-846 Method 8270.
6. Only compounds with a vapor instrusion standard are presented in this table.
7. Only compounds detected in one or more samples are presented in this table.
8. Only surface soil samples or unsaturated soil samples are presented in this table.
9. < = constituent not detected at a concentration above the reported detection limit. These results are also reported in gray.
10. NA = Not Analyzed.
11. Concentrations reported in milligrams per kilogram (mg/kg) or parts per million (ppm).
12. Soil standards obtained from the Pennsylvania Department of Environmental Protection (PADEP) Technical Guidance Manual for Vapor Instrusion (VI) into Buildings from Groundwater and Soil Under Act 2 dated November 19, 2016.
13. Shading indicates that the result exceeds the PADEP statewide health standard vapor intrusion screening value for non-residential soil.
14. Italics and bolding indicates that the result exceeds the PADEP statewide health standard vapor intrusion screening value for residential soil.
15. Brackets indicate the reported concentration of a duplicate sample.
16. Qualifier Definitions:
    B = Analyte is an estimated value between the instrument detection limit and the Reporting Limit.
    D = Concentration is based on a diluted sample analysis.
    J = Analyte is an estimated value.
    R = Data rejected during validation.
17. Data from 2018 and 2019 have undergone a Tier II validation. Data prior to 2018 have not been validated.

Notes:

1. Samples prior to 2018 were collected by Paulus, Sokolowski, and Sartor Engineering, PC on the dates indicated. Samples in 2018 and 2019 were collected by Arcadis on the dates indicated.
2. 2005 and 2006 samples were analyzed by Hampton-Clarke, Veritech Laboratories of Fairfield, New Jersey.
3. 2018 and 2019 samples were analyzed by SGS North America Incorporated Laboratories of Dayton, New Jersey.
4. Samples were submitted for laboratory analysis for one or more of the following constituent groups, as indicated above.
   - Target Compound List (TCL) volatile organic compounds (VOC) using United States Environmental Protection Agency (USEPA) SW-846 Method 8260.
   - TCL semi-volatile organic compounds (SVOC) using USEPA SW-846 Method 8270.
5. Only compounds with a vapor instrusion standard are shown in this table.
6. Only compounds detected in one or more samples are shown in this table.
7. < = constituent not detected at a concentration above the reported detection limit. These results are also reported in gray.
8. NA = Not Analyzed.
9. Concentrations reported in micrograms per liter (ug/L) or parts per billion (ppb).
10. Highest groundwater surface is the highest groundwater surface observed during the 2018 and 2019 monitoring well gauging events, except for values in black which are for wells that couldn't be located or were destroyed prior to the 2018 monitoring well gauging events. In these cases, the highest groundwater surface observed from 2005 and 2006 is reported.
11. Highest groundwater surface observed is reported in feet below ground surface (bgs).
12. Groundwater vapor intrusion standards obtained from the Pennsylvania Department of Environmental Protection (PADEP) Technical Guidance Manual for Vapor Instrusion (VI) into Buildings from Groundwater and Soil Under Act 2 dated November 19, 2016. Groundwater vapor intrusion standards are only applicable if groundwater is greater than 5 feet bgs.
13. Shading indicates an exceedance of either: (1) PADEP's non-residential groundwater vapor intrusion standard when groundwater surface is more than 5 feet bgs; or (2) PADEP's residential Medium Specific Concentrations (MSCs) for Used Aquifers containing Total Dissolved Solids (TDS) ≤ 2,500 milligrams per liter (mg/L) when groundwater surface is equal to or less than 5 feet bgs.
14. Italics and bolding indicates an exceedance of PADEP's residential groundwater vapor intrusion standard when groundwater surface is more than 5 feet bgs.
15. * indicates that the groundwater monitoring well was installed to replace the missing historical well also listed in the monitoring well ID.
16. Brackets indicate the reported concentration of a duplicate sample.
17. Qualifier Definitions:
    B = The compound has been found in the sample as well as its associated blank.
    D = Concentration is based on a diluted sample analysis.
    J = Analyte is an estimated value.
18. Data from 2018 and 2019 have undergone a Tier II validation. Data prior to 2018 have not been validated.

Table 22
Exposure Pathway Elimination

Remedial Investigation Report
National Grid Former Philadelphia Coke Plant
Philadelphia, Pennsylvania

Scenario Timeframe	Medium	Exposure Medium	Exposure Point	Receptor Population	Receptor Age	Exposure Route	Pathway Eliminated?	Rationale for Exposure Pathway Elimination by Cleanup Plan
Current	Soil	Surface Soil	Site	Outdoor Worker	Adult	Ingestion	Y	Surface soil outside of impervious areas is heavily vegetated. The limited areas of exposed surface soil may be contacted during activities such as lawn maintenance, but such maintance is limited to a few times per year and the grass height is kept at 6-inches or higher.
						Dermal Contact	Y	
						Inhalation	Y	
		Surface Soil	Site	Trespasser	Adolescent	Ingestion	Y	Surface soil outside of impervious areas is heavily vegetated. Site access is restricted by perimeter chainlink fencing and locked gates.
						Dermal Contact	Y	
						Inhalation	Y	
		Surface & Subsurface Soil	Excavation/Trench	Utility Worker	Adult	Ingestion	Y	Subsurface utilities at the Site were disconnected when the above-ground facilities and structures were demolished. There are no active utilities at the Site, other than one manhole providing access to the Upper Delaware Collecting Sewer that extends across the Site along the alignment of Bath Street. Work on the Upper Delaware Collecting Sewer would be performed by the Philadelphia Water Department, and potentially limited to access via the manhole, minimizing worker contact with soil. No soil excavation for installation, maintenance, or repair of underground utilities is anticipated under current conditions. Such work (if needed) and any remedial work would be conducted under a Health and Safety Plan (HASP) with engineering controls in-place to limit exposure. Work on the railroad that extends through the eastern portion of the Site (e.g., railroad tie replacement, ballast stone placement) would be performed by the railroad owner working from the railroad right-of-way, minimizing worker contact with soil beyond the railroad tracks.
						Dermal Contact	Y	
						Inhalation	Y	
	Groundwater	Shallow Groundwater	Excavation/Trench	Utility Worker	Adult	Ingestion	Y	Subsurface utilities at the Site were disconnected when the above-ground facilities and structures were demolished. There are no active utilities at the Site, other than one manhole providing access to the Upper Delaware Collecting Sewer that conveys regional stormwater deep beneath the Site along the alignment of Bath Street. The sewer does not collect any storm water from the Site. Based on measurements from the one existing manhole onsite, this sewer is very deep with an invert elevation at least 29 feet bgs. Future maintenance or repair of this sewer, if needed, could involve non-intrusive means (no excavation but potential access through an existing onsite manhole). No installation, maintenance, or repair of underground utilities is anticipated under current conditions. If such work were needed and required excavation to the depth of the perched water or groundwater table, the work would be conducted under a HASP with engineering controls in-place to limit exposure.
						Dermal Contact	Y	
						Inhalation	Y	
		Outdoor Air	Site	Outdoor Worker	Adult	Inhalation	Y	The volatile organic compound (VOC) concentrations identified in vadose zone soil and groundwater at the Site are less than those that would cause a vapor intrusion concern for outdoor air due to dispersion and mixing across a massive air volume.
Future	Soil	Surface Soil	Site	Outdoor Worker	Adult	Ingestion	Y	Under a redevelopment scenario, future Site workers may be exposed to surface soil. The installation of a cap consisting of development components, including concrete floor slabs/foundations for new buildings; asphalt pavement and/or concrete for driveways, parking areas, and sidewalks; and 2-feet of clean soil (e.g., in landscape areas) will restrict worker exposure to constituents of concern (COCs) in soils.
						Dermal Contact	Y	
						Inhalation	Y	
		Surface Soil	Workplace	Indoor Worker	Adult	Ingestion	Y	Under a redevelopment scenario, wind may generate dust from exposed soil at the Site and the airborne outside soils may be incidentally ingested or inhaled as volatiles and particulates outdoors (and to a lesser extent indoors as dust). However, the installation of a cap will eliminate exposure to COCs in soils.
						Dermal Contact	Y	
						Inhalation	Y	
		Surface Soil	Hypothetical Residence	Resident	Adult/Child	Ingestion	Y	Under a hypothetical residential redevelopment scenario, residents will not be exposed to soil because a cap consisting of development components, including concrete floor slabs/foundations for new buildings; asphalt pavement and/or concrete for driveways, parking areas, and sidewalks; and 2-feet of clean soil (e.g., in landscape areas) will restrict exposure to COCs in soils. Additionally, a deed restriction will limit the property to commercial or industrial use.
						Dermal Contact	Y	
						Inhalation	Y	
		Surface & Subsurface Soil	Excavation/Trench	Utility Worker	Adult	Ingestion	Y	Soil may be contacted during utility excavations for installation, maintenance, or repair of underground utilities. The installation of a cap, use of other engineering controls, and compliance with HASPs and Post-Remedial Care Plan restrict worker exposure to COCs in soils.
						Dermal Contact	Y	
						Inhalation	Y	
	Groundwater	Shallow Groundwater	Excavation/Trench	Utility Worker	Adult	Ingestion	Y	Construction/utility workers may encounter shallow groundwater during utility excavations for installation, maintenance, or repair of underground utilities. Volatile constituents in groundwater may volatilize into the utility trench. Potential exposures will be addressed by using personal protective equipment (PPE) in accordance with the HASP.
						Dermal Contact	Y	
						Inhalation	Y	
		Tapwater	Workplace	Indoor Worker	Adult/Child	Ingestion	Y	In the future, an environmental covenant will restrict groundwater use; therefore, no potable water wells may be installed at the Site once the covenant is in-place.
						Dermal Contact	Y	
						Inhalation	Y	
			Residence	Resident	Adult	Ingestion	Y	
						Dermal Contact	Y	
						Inhalation	Y	
		Indoor Air	Workplace	Indoor Worker	Adult	Inhalation	TBD	The VOC concentrations identified in vadose zone soil and groundwater at the Site could cause a vapor intrusion (VI) concern if mitigation systems were not installed. However, redevelopment plans will be required to include (1) a VI mitigation system(s) within areas of potential VI concern identified by initial VI screening ; or (2) building-specific VI risk assessment(s) that demonstrates that a mitigation system is not needed.
			Hypothetical Residence	Resident	Adult/Child	Inhalation	Y	

Notes:
1. Only potentially complete pathways from the conceptual site model are included in this table.

Abbreviations
COCs - constituents of concern
HASP - Health and Safety Plan
personal protective equipment - PPE
TBD - to be determined
VOC - volatile organic compound

2. IN A JULY 26, 1999 LETTER, PENNSYLVANIA DEPARTMENT OF ENVIRONMENTAL PROTECTION (PADEP) CONCLUDED THAT VOLATILE ORGANIC COMPOUND AND SEMI-VOLATILE ORGANIC COMPOUND CONCENTRATIONS IN GROUNDWATER SIGNIFICANTLY DECREASED FROM 1985 TO 1998 AND HAVE BEEN LOCALIZED SINCE 1994. THE CONCLUSION WAS BASED ON 14 YEARS OF GROUNDWATER SAMPLING FROM APRIL 1985 TO NOVEMBER 1998 AT MONITORING WELLS MW-1 THROUGH MW-6. DURING THIS TIME PERIOD, GROUNDWATER SAMPLES WERE GENERALLY COLLECTED ON A QUARTERLY BASIS (FOUR TIMES A YEAR).

- 1/2-MILE RADIUS OF SITE

GEOLOGIC UNIT

- QT - FILL DEPOSITS, HOLOCENE MARSH/ALLUVIAL DEPOSITS, AND TRENTON GRAVEL (PLEISTOCENE) FORMATION
- XW - WISSAHICKON FORMATION

NOTES:

1. GEOLOGIC DATA - THE U.S. DEPARTMENT OF AGRICULTURE (USDA), 2005, (ACCESSED VIA WEB ON MARCH 28, 2012).
2. WELL DATA - PA TOPOGRAPHIC & GEOLOGIC SURVEY DATABASE (ACCESSED VIA WEB ON OCTOBER 13, 2020).
3. PER THE PHILADELPHIA WATER DEPARTMENT RECORDS, RESIDENTS AROUND THE SITE CONSUME CITY WATER. ACCORDING TO THE PENNSYLVANIA GROUNDWATER INFORMATION SYSTEM WEBSITE, THE ONE DOMESTIC WELL LOCATED NEAR THE SITE IS ALSO LISTED FOR MONITORING. THE ONE DOMESTIC WELL IS LOCATED ON A PROPERTY WHERE THERE IS A HISTORICAL DIESEL RELEASE. THEREFORE, IT IS LIKELY THAT THIS WELL WAS USED FOR AND/OR CONTINUES TO BE USED FOR MONITORING PURPOSES ONLY. MORE INFORMATION IS AVAILABLE IN SUBSECTION 3.2.2.1 OF THE REMEDIAL INVESTIGATION REPORT.
4. WELLS OUTSIDE THE 1/2-MILE RADIUS OF THE SITE ARE NOT SHOWN.

Legend:

- ● = Complete Exposure Pathway.
- ◐ = Potentially Complete Exposure Pathway.
- ○ = Incomplete Exposure Pathway.
- -- = Not applicable.

NOTES:

Exposure pathway completeness is evaluated based on current and anticipated future use and

[a] Exposure route is currently incomplete due to vegetative cover and/or existing health and safety plan (HASP) requiring use of personal protective equipment (PPE) for ground intrusive / excavation work.

[b] Exposure route is currently incomplete for trespassers due to Site security fencing.

[c] Exposure route will be incomplete after a soil cover system and deed restriction are in place, limiting the property to commercial/industrial use (no fence will be required).

[d] Exposure route is incomplete due to the exising vegetative cover (or soil cover system to be installed during redevelopment) and/or exisiting HASP requiring use of PPE for ground-instrusive / excavation work. No passive recreational use will be allowed at the Site until after the soil cover system is installed, mitigating potential exposure.

[e] Exposure route will be incomplete due to a groundwater use ordinance to be established for the Site.

[f] Vapor intrusion (VI) exposure pathway will be fully assessed by a VI evaluation once the redevelopment plans are complete. Altenatively, a VI mitigation system can be installed in lieu of a VI evaluation that eliminates potential exposure pathways.

INTRODUCTION

Herpetological Associates, Inc. (HA) was contracted by Bohler Engineering on behalf of BP Bridesburg, LLC to conduct a Northern Red-bellied Cooter (*Pseudemys rubriventris*, Threatened) Phase I Aquatic and Nesting Habitat Survey for the proposed 4501 Richmond Street Project. The request for this survey was in response to a search of the Pennsylvania Natural Diversity Inventory (PNDI) database, which revealed a "Potential Impact" to a species under the jurisdiction of the Pennsylvania Fish and Boat Commission (PFBC). In response to the PNDI, a Species Impact Review (SIR) letter dated January 6, 2021 was issued by PFBC, which requested a habitat assessment for the Northern Red-bellied Cooter (formerly known as Eastern Redbelly Turtle) in the project area (PNDI #720080 [**Appendix A**]; SIR #53900 [**Appendix B**]).

MATERIALS AND METHODS

LOCATION OF THE STUDY SITE

The 66.5-acre project area is located in the city of Philadelphia, Philadelphia County, Pennsylvania. Site coordinates are 39.995449°, -75.068569°. The project area is found on the Camden U.S. Geological Survey (USGS) 7.5 minute quadrangle (**Figure 1**).

SURVEYORS

The Phase I survey was performed by Michael Torocco (Recognized Qualified Northern Red-bellied Cooter Surveyor (RQNRCS)) and Quillyn Bickley (Herpetologist).

HABITAT EVALUATION METHODS

HA reviewed publicly available data as part of a preliminary desktop review of potential, natural resources for the site, as well as wetland delineation maps that are developed specifically for the project. Data included information relating to soils; topography; waterways; floodplains; wetlands; and rare, threatened, and endangered species. Field evaluations of identified aquatic resources, including streams and ponds were conducted by an RQNRCS.

The Northern Red-bellied Cooter is a large, aquatic species that inhabits large ponds, lakes, and slow-flowing, deep-water streams (Carr, 1952). They are usually found in deep water with numerous basking sites and muddy or sandy substrate. Ample aquatic vegetation is important, as Northern Red-bellied Cooters are primarily herbivorous (Hulse et al., 2001; Swarth, 2003). The suitability of the site for this species is determined by evaluating the existing habitat components. Vegetative communities, hydrological conditions, topography, soil characteristics, and the surrounding upland habitat were investigated.

Figure 1. USGS topographic map showing the approximate location of the project site.

Habitat potential for Northern Red-bellied Cooter was determined by evaluating the size and depth of open water habitats, quantity of aquatic vegetation and stream or pond substrate type. The presence and orientation of basking sites are also noted. Potential aquatic habitat is defined in this report as either "temporary/transitional", which is marginal-quality habitatwhich may be used for short durations (generally less that one season) by migrating individuals; or "core habitat", which is permanent habitat that is can be used for multiple seasons by a local population.

Surveys for upland nesting habitat are conducted by first identifying potential aquatic turtle habitat. If a location is determined to provide suitable aquatic habitat, the upland areas surrounding the open water habitat are examined for potential nesting habitat. Locations which are determined to lack aquatic habitat or only provide transitional aquatic habitat are considered low potential for the presence of reproductive Northern Red-bellied Cooters, and therefore the surrounding upland areas are not considered potential terrestrial nesting habitat regardless of the upland characteristics. Areas within 500 feet of suitable aquatic habitat with ample sun exposure and well-drained soils are considered potential nesting habitat. Conversely, upland that surrounds suitable aquatic habitat and has heavy canopy cover, poorly drained soils, or contains impervious surfaces (e.g., concrete, asphalt) were not considered potential nesting habitat.

Due to the wide range of aquatic habitat and terrestrial nesting habitat used, an experienced RQNRCS evaluates the existing components of each habitat feature for Northern Red-bellied Cooter. Habitat data are recorded on custom field forms (*Phase I Northern Red-bellied Cooter Field Form*) that incorporate key habitat characteristics of the Northern Red-bellied Cooter. Separate field forms are prepared for aquatic and nesting habitat. Aquatic habitat data may be recorded at sample points, with sample point locations selected via an initial desktop review to provide suitable coverage of an aquatic feature. Sample points are generally selected at separate aquatic features (e.g., separate ponds/lakes, streams) within the project area, although multiple sample points may be selected to adequately cover a single, large aquatic feature. Photographs are taken to document important habitats or to document site conditions.

PROJECT AND SITE INFORMATION

Project/Property Name: 4501 Richmond Street Project

Project Area and Project Description: BP Bridesburg, LLC proposes to redevelop the existing 66.5-acre site, currently an undeveloped site, located at 4501 Richmond Street, Philadelphia, PA 19137. The existing site consists of mostly pervious land. The proposed development includes two (2) buildings with 740,701 square-feet (SF) and 148,611 SF of warehouse space. The site will also contain related site amenities and improvements inclusive of parking, access roadways, lighting, landscaping, utilities, and stormwater management facilities (**Appendix C**).

Regulated Wetlands and Watercourses: An investigation of the property was performed for wetlands and regulated watercourses by Valley Environmental Services, Inc. on October 15, 2020 and May 17, 2021. A plan showing the locations of wetlands and watercourses is provided in **Appendix D**.

Wetland/Stream Impacts: The on-site wetlands will be filled as part of site grading and remediation. An extension of the project area to the Delaware River is a proposed stormwater outfall. The project will be required to obtain Joint 105 permitting for the wetland disturbances and the outfall.

Current Land Use and Setting: The project area is located in a highly developed and historically altered urban setting within the City of Philadelphia. The site is currently fallow and naturally vegetated. A hazardous materials remediation site, the Philadelphia Coke Company Inc. (PCC) property, is located in the southern portion of the project area. Structures at the PCC site are dismantled and the site has been partially remediated, and is currently overgrown with trees and tall grasses. The project approaches the Delaware River, which is lined with bulkheads or old construction debris (concrete, brick, rock fill) in most locations.

Watershed: The project area is located within the Pompeston Creek-Delaware River HUC 12 watershed and the Tacony Creek-Frankford Creek HUC 8 watershed.

Area Investigated: The study area for the habitat assessment included the entire project area, but emphasis was placed on the Delaware River and upland areas within 300 feet of the river.

RESULTS

A Phase I survey for Northern Red-bellied Cooter was conducted on May 25, 2021. The primary emphasis of this study was to document the presence/absence of potential aquatic habitat and nesting habitat which could be impacted by the proposed project. Habitat photographs and a photo location map are presented in **Appendix E** and the *Phase I Northern Red-bellied Cooter Field Forms* are provided in **Appendix F**.

HABITAT DESCRIPTION

Project Area and Offsite Riverfront

The areas within and adjacent to the project area are highly disturbed, and are currently or formerly developed for commercial or industrial uses. Most sections of the upland riverfront were historically interspersed with wetlands and marshes, and were filled to accommodate this development. The former land use within the central project area was associated with the Philadelphia Coke Company, which was certified as closed in 1994 and is now in a state of natural succession; it is currently vegetated with early successional grasses, shrubs and trees, many of which are non-native and coverage is particularly dense. However, even areas which are currently naturally vegetated have impervious surfaces below a shallow soil layer. Fragments of macadam still remain in the northwest project area and old, gravel access roads weave through this successional area. A large transmission line right-of-way extends southwest to northeast, bisecting the eastern portion of the project area.

The upland along the Delaware River has been protected against flooding by the construction of bulkheads and fill, which produces an abrupt and steep transition to the water. A section of an abandoned railroad parallels the Delaware River outside and adjacent to the eastern project area. perimeter. To the south of the project area is a large bus company; and to the north is a large recycling center and a small, private marina.

Open canopy areas are limited to the abandoned railroad and the gravel access roads. Substrate in these areas is firm and compact and can be characterized as rock, gravel, with low organic content. With the exception of the gravel road and railroad tracks, vegetation is dense, including within the transmission line right-of-way. The large successional plot that occupies the majority of the project area contains thick herbaceous cover with scattered patches of trees and shrubs. Dominant species include mugwort (*Artemisia vulgaris*), unidentified grasses, crown vetch (*Coronilla varia*), bush honeysuckle (*Lonicera* sp.), staghorn sumac (*Rhus typhina*), and cottonwood (*Populus deltoides*).

Delaware River

The Delaware River in the vicinity of the project area is within the city limits of Philadelphia, and expectedly, is highly disturbed. The remnants of old piers and bulkheads are evident, as is the presence of fill material along the river bank from historic land alteration. The river at this location exhibits an inlet area with the presence of two linear bulkheads that extend approximately 500 feet

from the bank toward the river center. The inlet serves as a "cove" which is protected from the full force of the river flow. The river itself is approximately 2,650 feet wide, with observed water depths along the shoreline averaging 3-6 feet deep. Tidal fluctuations are on the order of 6 feet, which will expose portions of the river bottom of the assessed shoreline areas at low tide. Similarly, basking structure is limited to a few logs in protected area, since the high water flows periodically bring in and subsequently remove and logs or other structure in high-flow areas. Water quality is turbid. Substrate along the banks is composed of rock and gravel, with concrete and other various industrial debris scattered along its length - part of the fill that was historically placed to fill in marshes and low areas.

Submerged aquatic vegetation along the shoreline was not observed, but emergent vegetation grows sparsely among the rocks; the northernmost inlet supports spadderdock (*Nuphar advena*). The river bank is thickly vegetated with Japanese knotweed (*Reynoutria japonica*), common reed (*Phragmites australis*), staghorn sumac, indigo bush (*Amorpha fruticosa*), black walnut (*Juglans nigra*), and mulberry (*Morus* sp.).

HABITAT EVALUATION

Aquatic Habitat: The Delaware River along the project boundary provides potential core aquatic habitat for Northern Red-bellied Cooter. This assessment is based on the depth of the water (in excess of 3 feet), and protected/slow flow rate due to the presence of a cove. Limiting factors include limited basking structure and lack of aquatic vegetation. This section of river could support Northern Red-bellied Cooters, although it is assumed that they would move into and out of the area by way of the river throughout the season rather than being permanent residents.

One turtle, presumed to be a snapping turtle (*Chelydra serpentina*) but without positive identification, was observed swimming in the cove during the evaluation. Additionally, two beaver (*Castor canadensis*) were observed swimming.

Nesting Habitat: Several upland areas were identified as potential nesting habitat for Northern Red-bellied Cooter (**Appendix E1**). Locations with 1) lack of tree canopy, 2) substrate which is not excessively rock or overly compacted, and 3) proximity to the Delaware River (generally within 500 feet) were used as criteria for determining nesting potential. It should be noted that these areas are to the east and outside of the project area, and are not proposed to be disturbed by this project.

Within the project area the habitat consist of wooded areas and densely vegetated fields, which are unlikely to be used by nesting turtles. A network of trails could allow access to nesting turtles, but based on the distance from the river are not expected to be used.

RECOMMENDATIONS

Although nesting by turtles in the project area is not expected, a protective measure that can be utilized to eliminate the chance is the installation of a turtle exclusion fence. This is simply a silt or super silt fence barrier, which should extend along the entire eastern side of the project limit of disturbance (LOD). The fence should be buried six inches and provide a continuous barrier along the eastern LOD, and should remain in place for the duration of construction.

SUMMARY AND CONCLUSIONS

HA was contracted by Bohler Engineering on behalf of BP Bridesburg, LLC to conduct a Northern Red-bellied Cooter (*Pseudemys rubriventris*) Phase I Aquatic and Nesting Habitat Survey for the proposed 4501 Richmond Street Project. The project area is located in Phiadelphia City, Philadelphia County, Pennsylvania.

The Phase I habitat evaluation was conducted on May 25, 2021. The study area included the project area plus upland areas to the east and the Delaware River. The evaluation revealed potential core aquatic habitat within the Delaware River, but the presence of Northern Red-bellied Cooter at this location has not been confirmed. Potential nesting habitat was also observed in upland areas, particularly within 500 feet of the Delaware River; these location fall outside of the project area. Northern Red-bellied Cooters are not expected to nest or occur within the project area, but the installation of a turtle exclusion fence along the eastern LOD is recommended to further reduce the risk of this species within active construction areas.

THE ECOLOGY OF THE NORTHERN RED-BELLIED COOTER

Identifying Characteristics

The Northern Red-bellied Cooter (*Pseudemys rubriventris*; **Figures 2-3**) is a large basking turtle averaging 10-12 inches (254-305 mm) in carapace length when mature (Conant and Collins, 1991). Coloration and pattern are highly variable, but in general, the carapace is mahogany to black, with light chestnut to reddish vertical bars on the laminae (Iverson and Graham, 1990). The name *rubriventris* is from the Latin words *rubidus* or reddish, and *venter* for belly, referring to the reddish plastron (Graham, 1991).

Figure 2. Hatchling Northern Red-bellied Cooter.

Considerable sexual dimorphism exists in body size and scute proportions (Graham, 1991). Female red-bellied cooters are larger and have a longer plastron, higher shell and wider bridges, and plastral scutes are relatively longer at the midline, except the femoral scute, which is slightly longer in males. Red-bellied cooters, especially males, tend to become melanistic with age. Background color of the male plastron is pale pink overlaid with dark vermicular mottling; in females, it is coral red with grey figures narrowly bordering the plates (Graham, 1971b). The front of the upper jaw has a terminal notch flanked on each side by a distinct maxillary cusp. The presence of maxillary cusps distinguishes the redbelly group, which also includes the Florida Red-bellied Cooter *(P. nelsoni*) and the Alabama Red-bellied Cooter *(P. alabamensis*).

Status

Pennsylvania Status - Threatened
Federal Status - None

Range

The Northern Red-bellied Cooter has a relatively continuous coastal plain distribution across seven mid-Atlantic states from eastern North Carolina to central New Jersey, and a disjunct population in southeastern Massachusetts (Ernst and Barbour,1994). Waters (1962) suggests that the Massachusetts population may be a relic from a once continuous, prehistoric distribution across the eastern coastal United States. *P. rubriventris* could have expanded its range when the

Figure 3. An adult Northern Red-bellied Cooter.

continental shelf was emergent during the post-Wisconsin glacial period, which became isolated as the shelf submerged with the retreat of the glaciers. South of New England, the northernmost red-bellied cooter population known occurs in Middlesex County, New Jersey. Red-bellied cooters are also known historically from New York (Carr, 1952), and an introduced population apparently became established in Charleston, Staten Island, New York, R. Zappalorti, in Litt. 1992).

Habitat and Life History

Although most of their time is spent in fresh water ponds, Pennsylvania red-bellied cooters may also be found on land. In late spring and early summer, females select nesting sites in sandy soil, usually within 100 yards (90 m) of the pond. Females occasionally travel greater distances from the ponds in search of suitable nesting sites. In each nest, 8-35 eggs are deposited Hulse et al;., 2001). Incubation takes 73-80 days at 25°C (Graham, 1971a, 1971b). Hatchlings average about 1.25 inches (32 mm) in length (range 25.8-40.8 mm). Under certain conditions, hatchlings do not emerge from nests to enter ponds and instead overwinter in the nest chamber. Sexual maturity in red-bellied cooters is probably reached at 15 years by females and sooner by males.

Red-bellied cooters are usually active from late March to November. During the winter, they rest on the bottom of ponds under the ice, in a state of relative inactivity known as brumation. Current data gathered suggests that aquatic vegetation is the primary diet for all ages classes.

Factors Contributing to the Threatened Status in Pennsylvania

The Pennsylvania Fish and Boat Commission, with the advice of a team of herpetologists, generally considered the following factors that may adversely affect the red-bellied cooter and its habitat: adverse modification of water quality, such as siltation from land clearing adjacent to ponds; pollution and eutrophication of ponds; pollution of groundwater or reduction in the levels of ponds from groundwater pumping; any draining or filling of wetlands adjacent to occupied ponds; and shoreline modification such as filling, dredging for beaches, dikes, real estate development or similar types of activity (Graham, 1984; U.S. Fish and Wildlife Service, 1994). Other factors include:

1. Predation of eggs by raccoons and striped skunks, whose population tend to increase with residential development and habitat fragmentation;
2. Predation on hatchlings and young turtles from introduced and natural predators, such as largemouth bass, herons, bullfrogs, etc.;
3. Loss of nesting and basking sites to development, recreation, and forest canopy closure;
4. Manipulation of aquatic vegetation, including herbicide use, which may impact quality and quantity of food resources;
5. Collection and harassment by humans;
6. Incidental mortality from highway traffic and shooting;
7. Isolation of populations resulting in inbreeding and genetic drift, which can reduce genetic variability and potentially decrease survivorship.

1. PROJECT INFORMATION

Project Name: **4501 Richmond Street Philadelphia**
Date of Review: **10/15/2020 04:12:50 PM**
Project Category: **Development, Other**
Project Area: **64.69 acres**
County(s): **Philadelphia**
Township/Municipality(s): **PHILADELPHIA**
ZIP Code: **19137**
Quadrangle Name(s): **CAMDEN**
Watersheds HUC 8: **Lower Delaware**
Watersheds HUC 12: **Pompeston Creek-Delaware River; Tacony Creek-Frankford Creek**
Decimal Degrees: **39.995449, -75.068569**
Degrees Minutes Seconds: **39° 59' 43.6172" N, 75° 4' 6.8479" W**

2. SEARCH RESULTS

Agency	Results	Response
PA Game Commission	No Known Impact	No Further Review Required
PA Department of Conservation and Natural Resources	No Known Impact	No Further Review Required
PA Fish and Boat Commission	**Potential Impact**	**FURTHER REVIEW IS REQUIRED, See Agency Response**
U.S. Fish and Wildlife Service	No Known Impact	No Further Review Required

As summarized above, Pennsylvania Natural Diversity Inventory (PNDI) records indicate there may be potential impacts to threatened and endangered and/or special concern species and resources within the project area. If the response above indicates "No Further Review Required" no additional communication with the respective agency is required. If the response is "Further Review Required" or "See Agency Response," refer to the appropriate agency comments below. Please see the DEP Information Section of this receipt if a PA Department of Environmental Protection Permit is required.

3. AGENCY COMMENTS

Regardless of whether a DEP permit is necessary for this proposed project, any potential impacts to threatened and endangered species and/or special concern species and resources must be resolved with the appropriate jurisdictional agency. In some cases, a permit or authorization from the jurisdictional agency may be needed if adverse impacts to these species and habitats cannot be avoided.

These agency determinations and responses are **valid for two years** (from the date of the review), and are based on the project information that was provided, including the exact project location; the project type, description, and features; and any responses to questions that were generated during this search. If any of the following change: 1) project location, 2) project size or configuration, 3) project type, or 4) responses to the questions that were asked during the online review, the results of this review are not valid, and the review must be searched again via the PNDI Environmental Review Tool and resubmitted to the jurisdictional agencies. The PNDI tool is a primary screening tool, and a desktop review may reveal more or fewer impacts than what is listed on this PNDI receipt. The jursidictional agencies **strongly advise against** conducting surveys for the species listed on the receipt prior to consultation with the agencies.

PA Game Commission

RESPONSE:

No Impact is anticipated to threatened and endangered species and/or special concern species and resources.

PA Department of Conservation and Natural Resources

RESPONSE:

No Impact is anticipated to threatened and endangered species and/or special concern species and resources.

PA Fish and Boat Commission

RESPONSE:

Further review of this project is necessary to resolve the potential impact(s). Please send project information to this agency for review (see WHAT TO SEND).

PFBC Species: (Note: The Pennsylvania Conservation Explorer tool is a primary screening tool, and a desktop review may reveal more or fewer species than what is listed below.)

Scientific Name	Common Name	Current Status
Sensitive Species**		Endangered
Sensitive Species**		Endangered
Sensitive Species**		Threatened

U.S. Fish and Wildlife Service

RESPONSE:

No impacts to **federally** listed or proposed species are anticipated. Therefore, no further consultation/coordination under the Endangered Species Act (87 Stat. 884, as amended; 16 U.S.C. 1531 et seq. is required. Because no take of federally listed species is anticipated, none is authorized. This response does not reflect potential Fish and Wildlife Service concerns under the Fish and Wildlife Coordination Act or other authorities.

* Special Concern Species or Resource - Plant or animal species classified as rare, tentatively undetermined or candidate as well as other taxa of conservation concern, significant natural communities, special concern populations (plants or animals) and unique geologic features.
** Sensitive Species - Species identified by the jurisdictional agency as collectible, having economic value, or being susceptible to decline as a result of visitation.

WHAT TO SEND TO JURISDICTIONAL AGENCIES

If project information was requested by one or more of the agencies above, upload* or email* the following information to the agency(s). Instructions for uploading project materials can be found here. This option provides the applicant with the convenience of sending project materials to a single location accessible to all three state agencies. Alternatively, applicants may email or mail their project materials (see AGENCY CONTACT INFORMATION).

Check-list of Minimum Materials to be submitted:
____Project narrative with a description of the overall project, the work to be performed, current physical characteristics of the site and acreage to be impacted.
____A map with the project boundary and/or a basic site plan(particularly showing the relationship of the project to the physical features such as wetlands, streams, ponds, rock outcrops, etc.)
In addition to the materials listed above, USFWS REQUIRES the following
____**SIGNED** copy of a Final Project Environmental Review Receipt

The inclusion of the following information may expedite the review process.
____Color photos keyed to the basic site plan (i.e. showing on the site plan where and in what direction each photo was taken and the date of the photos)
____Information about the presence and location of wetlands in the project area, and how this was determined (e.g., by a qualified wetlands biologist), if wetlands are present in the project area, provide project plans showing the location of all project features, as well as wetlands and streams.

4. DEP INFORMATION

The Pa Department of Environmental Protection (DEP) requires that a signed copy of this receipt, along with any required documentation from jurisdictional agencies concerning resolution of potential impacts, be submitted with applications for permits requiring PNDI review. Two review options are available to permit applicants for handling PNDI coordination in conjunction with DEP's permit review process involving either T&E Species or species of special concern. Under sequential review, the permit applicant performs a PNDI screening and completes all coordination with the appropriate jurisdictional agencies prior to submitting the permit application. The applicant will include with its application, both a PNDI receipt and/or a clearance letter from the jurisdictional agency if the PNDI Receipt shows a Potential Impact to a species or the applicant chooses to obtain letters directly from the jurisdictional agencies. Under concurrent review, DEP, where feasible, will allow technical review of the permit to occur concurrently with the T&E species consultation with the jurisdictional agency. The applicant must still supply a copy of the PNDI Receipt with its permit application. The PNDI Receipt should also be submitted to the appropriate agency according to directions on the PNDI Receipt. The applicant and the jurisdictional agency will work together to resolve the potential impact(s). See the DEP PNDI policy at https://conservationexplorer.dcnr.pa.gov/content/resources.

5. ADDITIONAL INFORMATION

The PNDI environmental review website is a preliminary screening tool. There are often delays in updating species status classifications. Because the proposed status represents the best available information regarding the conservation status of the species, state jurisdictional agency staff give the proposed statuses at least the same consideration as the current legal status. If surveys or further information reveal that a threatened and endangered and/or special concern species and resources exist in your project area, contact the appropriate jurisdictional agency/agencies immediately to identify and resolve any impacts.

For a list of species known to occur in the county where your project is located, please see the species lists by county found on the PA Natural Heritage Program (PNHP) home page (www.naturalheritage.state.pa.us). Also note that the PNDI Environmental Review Tool only contains information about species occurrences that have actually been reported to the PNHP.

RE: Species Impact Review (SIR) – Rare, Candidate, Threatened and Endangered Species
PNDI Search No. 720080_1
4501 Richmond Street Philadelphia
PHILADELPHIA County: Philadelphia City

Dear Jason Mease:

This responds to your inquiry about a Pennsylvania Natural Diversity Inventory (PNDI) Internet Database search "potential conflict" or a threatened and endangered species impact review. These projects are screened for potential conflicts with rare, candidate, threatened or endangered species under Pennsylvania Fish & Boat Commission jurisdiction (fish, reptiles, amphibians, aquatic invertebrates only) using the Pennsylvania Natural Diversity Inventory (PNDI) database and our own files. These species of special concern are listed under the Endangered Species Act of 1973, the Wild Resource Conservation Act, and the Pennsylvania Fish & Boat Code (Chapter 75), or the Wildlife Code.

Northern Red-bellied Cooter (*Pseudemys rubriventris*, Threatened)

The Northern Red-bellied Cooter is one of Pennsylvania's largest native aquatic turtles. This turtle species is known to inhabit relatively large, deep streams, rivers, ponds, lakes, and marshes with permanent water and ample basking sites. Red-bellied Cooters are restricted to the southcentral and southeastern regions of the Commonwealth. The existence of this turtle species is threatened by habitat destruction, poor water quality and competition with aggressive non-native turtle species that share its range and habitat (e.g. Red-eared Slider).

Based on the review of this information and the proximity of the project to known element occurrences of the species of concern listed above, potential habitat could be present within the proposed disturbance area. Therefore, additional evaluations are necessary to confirm whether or not the project site contains habitat and to determine the potential for adverse impacts to this species. We request completion of a **habitat assessment** to characterize and determine if potential habitat exists within the vicinity of the proposed project area.

A qualified biologist, who possesses the necessary Scientific Collector's Permit issued by the Pennsylvania Fish and Boat Commission, must conduct this habitat assessment. A list of biologists recognized as qualified by the Pennsylvania Fish and Boat Commission to perform this assessment is enclosed.

This response represents the most up-to-date summary of the PNDI data and our files and is valid for two (2) years from the date of this letter. An absence of recorded species information does not necessarily imply species absence. Our data files and the PNDI system are continuously being updated with species occurrence information. Should project plans change or additional information on listed or proposed species become available, this determination may be reconsidered, and consultation shall be re-initiated.

If you have any questions regarding this review, please contact Kathy Gipe at 814-359-5186 and refer to the SIR # 53900. Thank you for your cooperation and attention to this important matter of species conservation and habitat protection.

Sincerely,

Christopher A. Urban, Chief
Natural Diversity Section

Phase I Red-bellied Cooter Field Forms

Phase I Northern Red-bellied Cooter Field Form - Aquatic Habitat

Project Name: 4501 Richmond Project No. PA20.09 Date: 5/25/2021
Township: Phila. City County: Phila. State: PA
GPS Datum: WGS84 Qualified Surveyor: M. Torocco Assistants: Q. Bickley

	Name/ID: Del. River	Notes:
Latitude (N)	39.99344	
Longitude (W)	75.06575	
Adjacent Potential Habitat?	yes	Delaware River
Setting	☐ Rural ☐ Suburban ☒ Urban	
Recreational Disturbance	☒ Low ☐ Moderate ☐ High	
Development/ Other Disturbance	☐ Low ☐ Moderate ☒ High	Highly disturbed riverfront and old industrial site
Alteration Time	☒ >20 y ears ☐ 2-19 years ☐ Present-2 years	

Aquatic Feature (*Only one aquatic feature evaluated per data form - use additional forms for separate features*)

Type: Select One Feature for Evaluation	Waterway:	☐ N/A ☐ Canal ☐ Unnamed Tributary ☒ Major River/Large Stream ☐ Other:_____	Delaware Rivers
	Open Water POW:	☒ N/A ☐ Pond ☐ Lake ☐ Oxbow ☐ Artificial Basin ☐ Other:_____	
	Wetland:	☒ N/A ☐ PEM ☐ PSS ☐ PFO	

Aquatic Feature Description

Size/Dimensions:	2500'-3000' wide	~1,300' of riverbank
Water Depth:	tidal, 2+ ft	estimated 3-6' deep
Water Quality/Turbidity:	turbid	
Substrate:	Rock, silt, concrete	
Aquatic Vegetation:	None	
Banks:	Eroded 3'	variable based on tide
Basking Structure:	limited- few logs	
Canopy Closure:	low	
Flow Rate (Waterway):	slow	bulk heads
Distance to Open Water (if wetland):	N/A	

Dominant Vegetation (Vicinity of Aquatic Feature)

Disturbance to Vegetation?	
Herbaceous Vegetation:	Jap. knotweed, mugwort, phragmites
Woody Vegetation:	indigo bush, staghorn sumac
Trees:	black willow, mulberry, cottonwood

Evaluation

Aquatic Habitat Quality	☒ **Core/Permanent** - ☐ Suitable ☒ Marginal ☐ **Temporary/Transitional** ☐ **No Habitat/Not Suitable**
Justification	Delaware River known occupancy for NBC's, bulkheads provide "cove" area, No SAV's observed

Notes: assessment area is at bulkhead cove along Del river front within abandoned, fallow industrial site. River is tidal, currently mid-tide. Eroded river front/bank formed by eroded old fill. Water depth gradually increases away from bank. No aquatic veg observed.

Semi-protected cove may provide aquatic habitat but turtles may have high immigration/emmigration rates.

Certification

As a Pennsylvania-Qualified Northern Red-Bellied Cooter Surveyor, I certify to the best of my knowledge that all of the information provided herein is accurate and complete.

Print Name Michael Torocco **Signature** [signature]

Phase I Northern Red-bellied Cooter Field Form - Nesting Habitat

Project Name: 4501 Richmond Project No. PA20.09 Date: 5/25/2021
Township: Phila, City County: Philadelphia State: PA
GPS Datum: WAS84 Qualified Surveyor: Mike Torocco Assistants: Q. Bickley

	Name/ID: Adj. Upland	Notes:
Latitude (N)	39.993786	
Longitude (W)	75.066704	
Adjacent Potential Habitat?	Yes - aquatic	Delaware River
Setting	☐ Rural ☐ Suburban ☒ Urban	
Recreational Disturbance	☒ Low ☐ Moderate ☐ High	
Development/ Other Disturbance	☐ Low ☐ Moderate ☒ High	
Alteration Time	☒ >20 y ears ☐ 2-19 years ☐ Present-2 years	

Nesting Habitat

	Name/ID: Adj. Upland	Notes: Primarily offsite area to east
Type (*check all that apply*)	☐ N/A or None ☐ Stream Bank ☒ ROW ☒ Gravel Road/Lot ☐ Paved Road Edge ☐ Lawn ☒ Old Field ☐ Ag Field ☒ Other: RR tracks	large successional field/forest bisected w/ gravel access road, transmission line & RR
Size	see description	
Distance to Aquatic Habitat	adj. → 500 ft	
Canopy Closure	☐ None ☐ Low ☒ Moderate	
Substrate (*check all that apply*)	☒ Rock ☒ Gravel ☐ Sand ☐ Clay ☐ Silt ☐ High organic ☒ Low organic ☐ Mulch ☐ Other:	
Relative Elevation	☐ Low ☒ Moderate ☐ High	
Soil Drainage	☐ Poor ☒ Moderate ☐ Well-drained	
Disturbance to Habitat	Yes	periodic ROW maintenance, occassional use of gravel roads to access groundwater meters

Dominant Vegetation

Disturbance to Vegetation?	Periodic ROW maintenance
Herbaceous Vegetation:	Grasses, Mugwort, vetch
Woody Vegetation:	Bush honeysuckle
Trees:	Cottonwood

Evaluation

Nesting Habitat Quality	☐ Suitable ☒ Marginal ☐ No Habitat	Justification: Poor access, extent of historical disturbances

Notes: Project area contains large successional plot that supports dense vegetation. Large areas of exposed Macadam present as well as shallow, compact soil over impervious surfaces. Few areas of open-canopy may provide Marginal potential nesting habitat which include abandoned rail road, gravel access road and open-canopy area near river. Substrate is gravel w/ low organic composition. Steep, eroded bank may present access challenge to these areas.

Certification

As a Pennsylvania-Qualified Northern Red-Bellied Cooter Surveyor, I certify to the best of my knowledge that all of the information provided herein is accurate and complete.

Subject: Proposed Post Remediation Care Plan
4501 Richmond Avenue, Philadelphia, Pennsylvania

Attainment of the Act 2 Site Specific Standard relies on both engineering and institutional controls. The objective of this Post Remediation Care Plan (PRCP) is to ensure the continued attainment with the Site-Specific Standard in the future and to address select comments from the Pennsylvania Department of Environmental Protection (PADEP) on January 14, 2022 based on their review of the Remedial Investigation Report and Cleanup Plan prepared by Arcadis US, Inc. (Arcadis). The PRCP may be modified in the future to comply with future changes in applicable legal requirements, subject to approval by PADEP.

In accordance with the Act 2 regulations, following PADEP approval of a Final Report, an Environmental Covenant (EC) will be executed between the property owner and the PADEP and recorded with the deed for the property. The EC will include activity and use limitations (AULs) and compliance reporting requirements. Those items are described below, along with vapor mitigation and soil management plans.

Environmental Covenant

The EC will be prepared in a similar format to the PADEP "Model Environmental Covenant" shown in **Attachment A**. The EC will be submitted to the PADEP for approval within 30 days following approval of the Final Report. Following PADEP approval of the EC, it will be recorded with the property deed and proof of filing with the deed office will be provided to the PADEP. The AULs and compliance monitoring and reporting requirements to be included in the EC are described below.

Activity and Use Limitations

The EC will contain the following language pertaining to AULs:

"The Property is subject to the following activity and use limitations, which the then current owner of the Property, and its tenants, agents, employees and other persons under its control, shall abide by:

- The groundwater beneath the Site shall not be used for any purpose;
- Subsurface structures such as basements shall not be constructed on Site;
- New enclosed structures shall be constructed with vapor mitigation measures as indicated in the Post Remediation Care Plan presented in the Act 2 Final Report; and
- The cover system shall be maintained as described in the Post Remediation Care Plan presented in the Act 2 Final Report."

Compliance Reporting

The EC will contain the following language relating to compliance reporting:

"Starting in the first month following recordation of this Environmental Covenant and biennially after that for two subsequent events, or after written request by the Department following the Department's approval of this Environmental Covenant, the then current owner of the Property shall submit, to the Department, written documentation presenting the results of compliance monitoring described in the Act 2 Final Report and stating whether or not the activity and use limitations in this Environmental Covenant are being abided by.

In addition, within 1 month after any of the following events, the then current owner of the Property shall submit, to the Department, written documentation of:

- Noncompliance with the activity and use limitations in this Environmental Covenant;
- Transfer of the Property;
- Changes in use of the Property; or
- Filing of applications for building permits for the Property and any proposals for any site work, if the building or proposed site work will affect the contamination on the Property subject to this Environmental Covenant."

Passive Indoor Vapor Mitigation

New enclosed structures shall be designed and constructed in general accordance with Section II-B of the approved Act 2 Cleanup Plan that relates to passive vapor mitigation **(Attachment B)**.

Any future building slabs shall be considered part of the vapor mitigation system in that they keep the vapor from entering the buildings directly. Absent another mitigating vapor intrusion system, the owner should ensure that there are no punctures or openings in the slabs, and that any openings such as pipes, electrical wires or other building elements are sealed with rubber gaskets, spray foam, or in some other way to prevent air from beneath the slabs from entering the living space. For inhabited buildings, a vapor barrier should be installed (at a minimum). Vapor intrusion mitigation measures are not needed for uninhabited structures (e.g., storage shed).

Cover System Monitoring and Maintenance

The cover system functions by restricting human access to impacted materials located beneath the cover. Currently, the cover system will be comprised primarily of a minimum of two feet of clean soil and to a lesser extent by concrete aggregate and paving. It is anticipated that in the future, much of the Site will contain various structures and roadways.

A visual inspection of the two-foot clean soil cap will be performed annually to look for perceived settlement against rigid elements (buildings, retaining walls, storm structures, etc.). If settlement is perceived, a further inspection which may include intrusive testing (i.e. measuring of total thickness by limited spot excavation) or surveying by a professional surveyor will be performed. Additional soil will be added if needed to re-establish the two-foot minimum thickness.

The owner will inspect the cover system quarterly and after significant rainfall events during the first year. Once vegetation is established, the inspection frequency will be reduced to annually, or as required by a ny subsequent permit. The table below identifies the general items to be inspected.

Inspection Item	Likely Corrective Measures
Vegetative Cover	Revegetate as needed
Soil Cover Erosion	Replace with clean soil to ensure the minimum two feet cover thickness and reseed
Pavement	Repair or replace any pavement that exposes underlying Site soil; also performing crack repairs as needed
Storm Water Management Structures	Remove obstructions to allow free drainage and repair any erosion damage
Building Slabs Over Vapor Mitigation Systems	Seal cracks and replace sealant that has separated or deteriorated around cracks and pipe penetrations

Repairs to the cover system will be made promptly and the corrective action will be documented for inclusion in the Compliance Report. Only certified clean fill as defined by the PADEP Management of Fill Policy will be used to repair the soil cover system. A copy of the PADEP Management of Fill Policy is provided as **Attachment C**. The Clean Fill Certification form can be submitted online[1].

Upon completion of development activities, sediment basins are proposed to be installed to control overland stormwater flow. The basins will be lined with a 30-millimeter geomembrane liner. These facilities will be inspected on a quarterly basis and after rainfall event exceeding 3 inches within a 24-hour period of time for indications of a compromise of remedial measure integrity (e.g., excessive settlement, erosion, etc.). The inspections will be documented on an inspection log and maintained by property owner's representative. Required repairs will be made by qualified personnel and recorded on the Intrusive Work Notification and Documentation form. Completed forms will be maintained in on-site files. A narrative description and/or plan mark-up depicting the cross sections and details of the remedial measures must be documented in the inspection logs for any necessary repairs.

Soil Management Plan

Future excavation into and below the cover must be carefully planned and documented to ensure that:

1. The integrity of the remedial measures is maintained;
2. Construction workers are protected; and
3. Site soil is properly managed and disposed of.

The purpose of this Soil Management Plan, included as **Attachment D**, is to provide general guidelines to be considered when planning for and conducting excavation activities at the Site. In accordance with the proposed EC Compliance Reporting requirements described above, PADEP must be notified within 1 month following the application for building permits or any proposals for activities that "will affect the contamination at the property". Currently, all material beneath the cover system is considered to be potentially "contaminated". Therefore, PADEP must be notified of planned excavation activities beneath the cover and that notification must describe the plans relating to a specific activity for ensuring worker safety and managing the excavated material. Notification must be 15 days prior to initiating any activity that will disturb the soil cover and underlying potentially contaminated materials.

It is expected that excavation will occur using a variety of methods for a variety of reasons, including:

1. Construction of caissons through the unsaturated and saturated zone using large diameter augers;
2. Construction of building footers and foundations using heavy construction equipment; and
3. Installation of subsurface utilities.

[1] http://www.depgreenport.state.pa.us/CleanFill

Prospective contractors performing work that may disturb the soil cover and underlying Site Materials need to consider the following:

1) Work below the cover system may encounter hazardous substances. A site-specific health and safety plan should be developed to address work activity hazards and protection of the workers, including air monitoring and other media monitoring as appropriate.
2) Measures must be employed to ensure that materials from below the cover system do not impact the clean cover material in the vicinity of the work area;
3) Excavated material from below the cover may be used as backfill provided that 2 feet of clean soil cover and/or hard surface are re-established when the work is completed. Excavated material not suitable for reuse as subsurface fill must be properly characterized and disposed off-Site in accordance with 25 Pa Code § 250.3(a). Tar-like material may be encountered in certain locations during excavation. If immobile tar or tar-like material is encountered during construction, requiring removal from its present location, the material will be characterized and may remain on-Site if found to be non-hazardous. If potentially mobile tar or tar-like material (as determined by a paint filter test) is encountered during construction, it will be segregated and transferred to a material staging area constructed with a low-permeability liner system (e.g., HDPE) extending over the prepared ground surface and formed sidewalls to contain the tar/soil mixture. The stockpiled material will be characterized to determine disposal requirements and subsequently disposed of off-Site in accordance with 25 Pa. Code § 250.3(a);
4) Excess material that can't be placed under the cover requires waste characterization and off-Site disposal. No material removed from beneath the marker mat may remain uncovered.
5) Fill materials brought on Site must meet the definition of "clean fill" as presented in the PADEP Management of Fill Policy (**Attachment C)**.
6) Groundwater at the Site contains a variety of polycyclic aromatic hydrocarbons (PAHs), arsenic and lead in concentrations exceeding the PADEP Medium Specific Concentrations (MSCs). Excavation below the water table must include plans for managing and off-Site disposal of liquids.
7) A general NPDES storm water permit exists for the site. Close coordination with the property owner is necessary during design and execution of excavation to determine what type of modifications to the existing permit, if any, are necessary.

The following presents the generally anticipated sequence of events during excavation below the cover system.

Excavation

The PADEP must be notified prior to excavation into the soil below the cover system as required by the EC. The notification will include specific plans for ensuring worker safety; managing excavated materials; and restoring the clean cover system. Excavation below the cover system is expected to generally proceed in the following manner:

1) Obtain necessary permits, establish erosion and sediment controls, and implement health and safety measures as required.
2) Remove and stockpile the top 2 feet of clean cover.
3) Excavate into the potentially impacted material and stage on Site, separate from the clean cover. Depending on the size of the excavation, the excavated material could be placed on polyethylene sheeting, or the clean cover could be over excavated such that the excavated material is placed directly on other "sub cover" soils. Further containment measures are necessary for excavation below the water table.
4) Backfill the excavation with the stockpiled soil from below the cover. Stockpiled clean cover such that the 2-foot thickness of clean cover is restored or the material is beneath a hard surface (e.g., roadway, floor slab, etc.).
5) Obtain disposal facility approval (where applicable a RCRA-approved facility) and dispose of excess impacted soil off-Site at a properly permitted disposal facility. The disposal facility will provide specific instructions for sampling and analysis of the material for characterization.

The Site owner must maintain documentation relating to the location of the excavation and the disposition of the excess material, including waste disposal manifests. A summary of the excavation activities will be included in the annual Compliance Report as required by the EC.

Dust Control

Site development will be performed in accordance with a dust control permit issued as per § IX of the Philadelphia Air management Services Regulations set forth by the Philadelphia Department of Public Health's Air Pollution Control Board and other applicable permits and regulations. The dust control permit is required for earthwork (e.g., clearing, grubbing, or earth disturbances) involving more than 5,000 square feet of land.

During construction, Site controls, such as silt fencing, silt socks, stabilized construction entrances, wetting, tire washes, and street sweeping, will be conducted to minimize fugitive dust generation and soil movement off-Site.

Human Health Risk Assessment – Utility Worker

Pursuant to 25 Pa. § 250.602, Roux completed a limited Site-specific Human Health Risk Assessment (HHRA) to address select PADEP's comments from the January 14, 2022 letter based on their review of the Remedial Investigation Report and Cleanup Plan prepared by Arcadis. The HHRA has been developed to evaluate whether soil poses an unacceptable risk to human health given the proposed future work at the Site, specifically for utility workers at the Site as part of future redevelopment activities. The various pathways are addressed by pathway elimination, a combination of Statewide health and Site-specific numeric standards, and the calculation of residual risk based on current Site data. As detailed below, this evaluation includes the identification of regulated substances carried forward into the risk assessment as constituents of potential concern (COPCs), an exposure assessment discussing the relevant receptors and pathways, and details on inputs and derivation of specific risk calculations for COPCs in Site soil. This evaluation has been prepared as outlined in the January 2019 Technical Guidance Manual (TGM) and in accordance with 25 Pa. Code § 250.602(c), § 250.603 and 250.604.

Contaminants of Potential Concern (COPCs)

Pursuant to the aforementioned procedures, Roux attained analytical data from Arcadis for soil samples collected from surface soil and unsaturated soil. The analytical data was compared to the United States Environmental Protection Agency's (USEPA's) Industrial Regional Screening Levels (RSLs) to identify COPCs. The dataset included exceedances of several metals, polychlorinated biphenyls, volatile organic compounds, and semi-volatile organic compounds, as listed in **Table 1**.

The HHRA completed by Arcadis analyzes risk in a small portion of the Site (i.e., near the railroad). The COPCs identified by Roux represent Site-wide COPCs; therefore, Roux analyzed additional COPCs absent from Arcadis' HHRA analysis. From the analytical data provided by Arcadis, Roux utilized the ProUCL software Version 5.1 (2015a,b) to calculate the upper confidence limits (UCL) for the COPC list, as shown on **Table 2A,** by using the recommended output concentration.

Potentially Exposed Population and Exposure Pathways

For purposes of this limited HHRA, future exposure pathways to both surface (0 – 2 ft below ground surface [bgs]) and subsurface, unsaturated soils (2 – 16 ft bgs) were considered complete. This Post Remediation Care Plan includes the limited HHRA for only the future utility work at the Site since a majority of the Site is being raised; therefore, construction workers would not be cutting into the impacted soils. If it is anticipated that the construction worker will be cutting into impacted soils, the construction workers with either 1) have the proper 40-hour OSHA HAZWOPER training or 2) a human health risk assessment will be performed to evaluate risk for the construction worker exposure pathway. Exposure pathways

associated with direct contact with soil include incidental ingestion, dermal contact, and the inhalation of vapors and/or particulates during intrusive subsurface activities within a trench specifically for utility line installation. It is assumed during utility work groundwater will not be encountered and therefore groundwater exposure was not evaluated.

Toxicity Assessment

The toxicity assessment discusses the two general categories of toxic effects (noncarcinogenic and carcinogenic) and constituent-specific toxicity values used to calculate potential risks for these two types of toxic effects. Toxicity values used in the calculations and their sources are presented in **Table 2B**. Toxicity values for potential noncarcinogenic and carcinogenic effects were obtained by accessing the toxicity information contained in the current USEPA RSL tables (USEPA 2019b). Variables utilized as part of this HHRA are outlined on **Table 2C**.

Exposure Assumptions

The equations used to evaluate utility workers exposures to unsaturated soil are presented in **Table 2D** and are used to calculate an acceptable soil concentration that upon exposure will not pose an unacceptable risk to the potentially exposed population. The Excess Lifetime Cancer Risks (ELCRs) and Hazard Index (HI) for non-cancer effects were developed for all unsaturated soil COCs and are derived based on the most likely exposed population (utility worker) and exposure routes (ingestion, dermal absorption, and inhalation).

The exposure assumptions used in the calculations are presented in **Table 2E** and are summarized below. Utility workers are assumed to access the Site and have the potential to be exposed to surface soils through incidental ingestion, dermal contact, or inhalation. The body weight for an average worker is 80 kilograms, which is the weighted average of the mean recommended values for body weight by age group from the PADEP. The selected soil ingestion rate is 330 mg/day, which is the central tendency soil ingestion rate (USEPA 2002, Exhibit 1-2); and the fraction ingested from the Site is assumed to be 100 percent, which is conservative. Utility workers are assumed to work 5 days per week over a two-week period as part of utility work (FDOT, 2001) for one year. The assumed exposed skin surface area (SSA) is 3,527 centimeters squared (cm^2), which is the default for construction workers (USEPA 2002). The construction worker 0.3 milligram per square centimeter per day soil-to-skin adherence rate (SAR) from USEPA (2002, 2004) is used. The exposure time used in inhalation exposure equations is 8 hours per day based on typical work day.

Additional factors are required for the evaluation of the inhalation route. General approaches for the derivation of these factors are included in the *Supplemental Guidance for Developing Soil Screening Levels for Superfund Sites* (USEPA 2002). Volatilization factors derived following USEPA 2002, are shown in **Table 2F**. Particulate Emission Factor calculations for wind-blown fugitive dust are included in **Table 2F**.

Noncarcinogenic Effects

For a given regulated substance, the dose or concentration that elicits no adverse effect when evaluating the most sensitive response in the most sensitive species is referred to as the “no observed adverse effect level.” This level is used to establish noncancer toxicity values, called reference doses (RfDs) for evaluating oral exposures and reference concentrations (RfCs) for evaluating inhalation exposures. The RfD and RfC values represent daily exposure levels that are not expected to cause adverse noncarcinogenic health effects. **Table 2B** presents the available RfDs and RfCs for COCs. Chronic non-carcinogenic values are used in the derivation of HIs.

Carcinogenic Effects

Cancer slope factors (CSFs) are derived from the conservative assumption that any dose level has a possibility of causing cancer. The cumulative dose, regardless of the particular exposure period, determines the risk. To evaluate inhalation exposures, inhalation unit risks (IURs) that relate cancer potency to a constituent concentration in air are used. **Table 2B** presents the CSF and IUR for each constituent considered to be a carcinogen.

Dermal Toxicity Values

The USEPA has not yet developed toxicity values specific to dermal exposure. For this reason, the oral toxicity values (RfD_o and CSF_o) and the fraction absorbed dermally from soil, also known as the dermal absorption efficiency (ABS_d) were used to derive adjusted toxicity values (RfD_d and CSF_d) (adjusted to dermal dose) for use in assessing dermal exposure (USEPA 1989, 2004): **Table 2F** includes the dermal ECLR/HI calculations which incorporate the ABS_d into the equations, also presented in **Table 2B.**

Lead Modeling

There currently are no toxicity data for lead that allow a standard quantification of potential risks and hazards associated with lead exposure. Therefore, the USEPA (2003b, 2009, 2017) Adult Lead Methodology (ALM) was used to quantify potential risks and hazards associated with lead exposure at the Site. Specifically, the ALM was used to evaluate a utility worker scenario. Parameter values used in the ALM were based on USEPA's latest recommended default values. **Attachment E** presents the ALM model used to quantify risk following the latest updates to the ALM (USEPA 2017). The mean lead concentration of 905 mg/kg presents a 5.3% probability of a Target lead blood level of 5 µg/dL and a 0.3% probability of a target lead level of 10 µg/dL. Input values used by Roux are conservative and assume a full year of utility work. A more realistic scenario would assume an exposure of ten days over a two-week period. In addition, a majority of the elevated lead concentrations do not correspond with the depths in which the utility workers would be operating. Therefore, the probability of unacceptable lead blood level concentrations is likely much less likely.

Risk Evaluation

The evaluation of risk or the calculation of ELCR/HI requires the assumption of acceptable "target" risk levels for carcinogenic and non-carcinogenic effects. ELCRs were calculated for each COC and the total ELCR was compared to a target cancer risk of 1×10^{-5} as presented in **Table 2F**. A non-cancer hazard quotient (HQ) of 1 indicates that the exposure level is equal to the reference exposure level that is not expected to produce non-carcinogenic (systemic) effects, even for sensitive individuals or subpopulations. HQs were calculated for each COC and the total HI was compared to a target HI of 1, as presented in **Table 2F**. For carcinogens which also have available non-carcinogenic toxicity values, both the ELCR/HI were calculated based on potential carcinogenic (at a target risk level of 1×10^{-5}) and non-carcinogenic effects (at a target non-cancer HQ of 1).

Risk Characterization Results

The exposure variables and assumptions are presented in **Table 2E**. The equations used to calculate the ECLR/HI are presented in **Table 2D**. The dermal absorption parameters and volatilization factors are presented in **Table 2B** and **Table 2F**, respectively. Toxicity values are presented in **Table 2B**.

Due to conservative estimates, lead should not pose a concern to utility workers during subsurface work. In addition, total ECLR and total HI are below the target cancer risk of 1×10^{-5} and target non-cancer HQ of 1, respectively.

The Site-wide unsaturated soil EPCs are currently at acceptable or "safe" concentrations. There is no anticipated unacceptable risk to the only potentially complete exposure pathway of direct contact with soil

by utility workers. In the future, the pathway to soil COCs will be eliminated to other potential receptors through engineering and institutional controls as discussed in the Cleanup Plan.

Notes:
ft bgs = Feet below ground surface.
mg/kg = Milligrams per kilogram.
USEPA = United States Environmental Protection Agency.
Boxed concentrations exceed the EPA Industrial Soil Regional Screening Levels.
— = Sample not analyzed.
B = Analyte also detected in the laboratory blank.
D = Result reported from dilution analysis.
ND = Not detected.
U = Not detected above laboratory detection limit.
J = Result below the reporting limit (estimated value).
Bold = Detected concentration.

Table 1. Summary of Arcadis Soil Analytical Data. BP Bridesburg, LLC; 4501 Richmond Ave, Philadelphia, PA.

Sample ID	USEPA	TP-64
ft bgs	Industrial Soil	3
Sample Date	Regional Screening Level	3/21/2005
METALS - 6010D (mg/kg)		
Antimony	470	**4**
Arsenic	3	**16**
Chromium	—	**56**
Cyanide	150	**45**
Lead	800	**130**
Mercury	46	**0.54**
Selenium	5800	**3.6**
POLYCHLORINATED BIPHENYLS (mg/kg)		
Aroclor 1260	0.99	NA
SEMI-VOLATILE ORGANIC COMPOUNDS - 8270D (mg/kg)		
1,1-Biphenyl	200	—
2-Methylnaphthalene	3000	**13**
4-Methylphenol	16000	ND
Anthracene	230000	**100**
Benz(a)anthracene	21	**300**
Benzo(a)pyrene	2.1	**280**
Benzo(b)fluoranthene	21	**470**
Benzo(g,h,i)perylene	—	**100**
Benzo(k)fluoranthene	210	**130**
Carbazole	—	**31**
Chrysene	2100	**280**
Dibenz(a,h)anthracene	2.1	**40**
Dibenzofuran	1200	**42**
Fluoranthene	30000	**710**
Fluorene	30000	**59**
Indeno[1,2,3-cd]pyrene	21	**140**
Naphthalene	8.6	**43**
Phenanthrene	—	**340**
Phenol	250000	ND
Pyrene	23000	**460**
VOLATILE ORGANIC COMPOUNDS - 8260C (mg/kg)		
Benzene	5.1	ND

Notes:
ft bgs = Feet below ground surface.
mg/kg = Milligrams per kilogram.
USEPA = United States Environmental Protection Agency.
Boxed concentrations exceed the EPA Industrial Soil Regional Screening Levels.
— = Sample not analyzed.
B = Analyte also detected in the laboratory blank.
D = Result reported from dilution analysis.
ND = Not detected.
U = Not detected above laboratory detection limit.
J = Result below the reporting limit (estimated value).
Bold = Detected concentration.

Compound	ProUCL Recommended Output Concentration (mg/kg)
METALs	
Arsenic	30.36
Chromium	51.31

Variable	Definition
Θ_{as}	Air-filled porosity of the soil (unitless).
Θ_T	Total soil porosity (unitless).
Θ_{ws}	Water-filled porosity of the soil (unitless).
ρ_b	Dry soil bulk density (g/cm³).
ABSd	Dermal absorption efficiency (unitless).
ADAF	Age-Dependent Adjustment Factor for evaluation of risk from constituents with a mutagenicity mode of action.
AT_C	Averaging time for cancer effects (days).
AT_{NC}	Averaging time for non-cancer effects (days).
BW	Body weight (kg).
CF	Conversion factor 0.042 day/hr.
C_{sat}	Constituent saturation limit in soil (mg/kg).
CSF	Cancer slope factor for oral (CSF_o) or dermal (adjusted to an absorbed dose, CSF_a) exposure ($mg/kg/day^{-1}$).
D_A	Apparent diffusivity in soil (cm^2/sec).
D_{air}	Constituent diffusivity in air (cm^2/sec).
D_{wat}	Constituent diffusivity in water (cm^2/sec).
ED	Exposure duration (years).
EF	Exposure frequency (days/year).
ELCR	Excess lifetime cancer risk (unitless) from the following pathways: oral ($_o$), dermal ($_d$), and inhalation ($_i$).
EPCs	Exposure point concentration in soil (mg/kg).
ET	Exposure time (hr/day).
FI	Fraction ingested from area of concern (unitless).
Foc	Fraction organic carbon in the soil (unitless).
F(x)	Function of Ut/Um (unitless); $F(x) = 0.18 \times (8x^3 + 12x) \times \exp[-(x^2)]$, where $x = 0.886 \times (Ut/Um)$.
HI	Hazard index for non-cancer effects (unitless); sum of the HQs.
H_o	Dimensionless Henry's law constant (unitless); calculated as $H_o = H/RT$.
HQ	Hazard quotient for non-cancer effects (unitless) from the following pathways: oral ($_o$), dermal ($_d$), and inhalation ($_i$).
IRs	Ingestion rate of soil (mg/day).
IUR	Inhalation unit risk ($\mu g/m^3$).
Koc	Organic carbon partition coefficient (cm^3/g = mL/g = L/kg).
PEF_{wind}	Particulate emission factor due to wind (m^3/kg).
Q/C_{vol}	Volatile emission flux per unit concentration [$(g/m^2/sec)/(kg/m^3)$].
Q/C_{wind}	Particulate emission flux per unit concentration [$(g/m^2/sec)/(kg/m^3)$].
RBF	Relative bioavailability factor; constituent specific; default of 100% (i.e., 1) unless otherwise indicated (unitless). RBF for arsenic in soil was set at 60% (i.e., 0.6).
RfC	Reference concentration (mg/m^3).
RfD	Reference dose for oral (RfD_o) and dermal (adjusted to an absorbed dose, RfD_a), exposure (mg/kg/day).
RPF	Respirable particle fraction (0.036 $g/m^2/hr$).
SAR	Soil-to-skin adherence rate ($mg/cm^2/day$).
SSAs	Exposed skin surface area for soil contact (cm^2).
T	Exposure interval (sec).
VF-sl	Soil volatilization factor (m^3/kg).
x	Intermediate value in the calculation of PEF; $x = 0.886 \times (Ut/Um)$.

Notes:
atm = Standard atmosphere.
cm^2 = Square centimeter.
cm^3 = Cubic centimeter.
g = Gram.
hr = Hour.
K = Kelvin.
kg = Kilogram.
L = Liter.
m = Meter.
m^2 = Square meter.
m^3 = Cubic meter.
mg = Milligram.
mL = Milliliter.
mol = Mole.
sec = Second.
µg = Microgram.

		Equations
Oral:		
	$ELCR_o$ or HQ_o =	$\frac{EPCs \times RBF \times ADAF \times FI \times IR_S \times EF \times ED}{(10^6\ mg/kg) \times BW \times (AT_C \text{ or } AT_{NC}) \times ([1/CSF_o] \text{ or } RfD_o)}$
Dermal:		
	$ELCR_d$ or HQ_d =	$\frac{EPCs \times ADAF \times SSAs \times SAR \times ABSd \times EF \times ED}{(10^6\ mg/kg) \times BW \times (AT_C \text{ or } AT_{NC}) \times ([1/CSF_d] \text{ or } RfD_d)}$
Inhalation:		
	$ELCR_i$ or HQ_i =	$\frac{EPCs \times ADAF \times ET \times CF \times EF \times ED}{(VF\text{-}sl) \times (AT_C \text{ or } AT_{NC}) \times ([1/IUR \times 10^{-3}\ mg/\mu g] \text{ or } RfC)}$
(Volatiles)	**VF-sl =**	$\frac{Q/C_{vol} \times [3.14 \times D_A \times T]^{1/2}}{2 \times \rho_b \times D_A \times (10{,}000\ cm^2/m^2)}$
	D_A =	$\frac{[(\Theta_{as}^{10/3} \times D_{air} \times H_o) + (\Theta_{ws}^{10/3} \times D_{wat})]/\Theta_T^2}{(\rho_b \times Koc \times Foc) + \Theta_{ws} + (\Theta_{as} \times H_o)}$
(Non-Volatiles)	**PEF =**	$\frac{Q/C_{wind} \times (3{,}600\ sec/hr)}{RPF \times (1\text{-}V) \times (Um/Ut)^3 \times F(x)}$
Total Cancer Risk:		
	ELCR =	$ELCR_o + ELCR_d + ELCR_i$
Total Non-Cancer Hazard:		
	HI =	$HQ_o + HQ_d + HQ_i$

Notes:
C = Celsius.
cm^2 = Square centimeter.
hr = Hour.
kg = Kilogram.
m^2 = Square meter.
mg = Milligram.
sec = Second.
µg = Microgram.

Variable	Value	Unit	Source
Θ_{as}	0.284	[ ]	= Θ_T - Θ_{ws}.
Θ_T	0.387	[ ]	Total soil porosity for silty clay (USEPA 2004).
Θ_{ws}	0.103	[ ]	Water-filled soil porosity for silty clay (USEPA 2004).
ρ_b	1.62	g/cm^3	Soil dry bulk density for silty clay (USEPA 2004).
ADAF	1	[ ]	Age-Dependent Adjustment Factor for evaluation of risk from constituents with a mutagenicity mode of action (USEPA 2021).
AT_C	25,550	days	Average time for cancer risk is the expected lifespan of 70 years (USEPA 1989 and 2014).
AT_{NC}	365	days	Average time for non-cancer risk is the total exposure duration (USEPA 1989 and 2014).
BW	80	kg	PADEP default body weight.
CF	0.042	day/hr	Conversion for 24 hours in 1 day.
ED	1	year	Assumes one year of construction.
EF	10	days/year	The average duration for work projects utilizing a trench is 2 weeks (5 days/week) (FDOT 2001).
ET	8	hr/day	Assumes 8 hour work days.
FI	1	[ ]	Professional judgement.
Foc	0.002	[ ]	Fraction organic carbon (USEPA 2002 default).
F(x)	0.0759	[ ]	Function of x (USEPA 2002b default).
IRs	330	mg/day	Recommended value for construction worker (USEPA 2002, Exhibit 1-2)
Q/C_{vol}	68.18	(g/m^2/sec)(kg/m^3)	Volatilization flux per unit concentration under passive conditions (USEPA 2002 default).
Q/C_{wind}	93.77	(g/m^2/sec)(kg/m^3)	Volatilization flux per unit concentration under soil invasive conditions (USEPA 2002b default).
RPF	0.036	g/m^2/hr	Respirable particle fraction (USEPA 2002b default).
RT	0.02447	atm-m^3/mol	Calculated with T = 298.15 K.
SAR	0.3	mg/cm^2/event	Recommended value for construction worker (USEPA 2002, 2004), assumed same for utility worker.
SSAs	3,527	cm^2	Recommended value for construction worker (USEPA 2002), assumed same for utility worker.
T	3.15E+07	sec	Exposure interval based on 1 year.
TCR	1.00E-05	[ ]	Target cancer risk value (USEPA 2021).
THQ	1	[ ]	Target hazard quotient value (USEPA 2021).
U_m	4.16	m/sec	Mean annual wind speed for Philadelphia, PA (NOAA 2018).
U_t	11.32	m/sec	Equivalent threshold value of windspeed at 7 meters (USEPA 2002b default).
V	0.75	[ ]	Fraction vegetative cover (default = 0.5, site-specific = 0.75).
x	2.411	[ ]	Function of U_t/U_m (USEPA 2002b default).

ENVIRONMENTAL COVENANT

This Environmental Covenant is executed pursuant to the Pennsylvania Uniform Environmental Covenants Act, Act No. 68 of 2007, 27 Pa. C.S. §§ 6501 – 6517 (UECA). This Environmental Covenant subjects the Property identified in Paragraph 1 to the activity and/or use limitations in this document. As indicated later in this document, this Environmental Covenant has been approved by the Pennsylvania Department of Environmental Protection (Department).

1. **Property affected**. The property affected (Property) by this Environmental Covenant is located in_____ (name of municipality), _____ County.

The postal street address of the Property [if any] is: _____.
The latitude and longitude of the center of the Property affected by this Environmental Covenant is: [either decimal degrees (DD.DDDDDD) or DD/MM/SS or DD/MM/SS.SSSS; preferred is decimal degrees] _____.
The Property has been known by the following name(s): _____
[For registered tanks, the PADEP Tank Facility ID# is:_____
[For other facilities, the DEP Primary Facility ID# is/are: _____

A complete description of the Property is attached to this Environmental Covenant as Exhibit A. A map of the Property is attached to this Environmental Covenant as Exhibit B.

[Use when Grantor & Grantee are the same, i.e., when Grantor is the only holder.]

2. **Property Owner / GRANTOR / GRANTEE**. _____ is/are the owner(s) of the Property and the GRANTOR and GRANTEE of this Environmental Covenant.

3. The mailing address(es) of the owner(s) is/are: _____.

[Use when there are holders other than Grantor.]

2. **Property Owner / GRANTOR**. _____ is/are the owner(s) of the Property and the GRANTOR of this Environmental Covenant.

3. **Holder(s) / GRANTEE(S)**. The following is/are the GRANTEE(s) and a "holder," as that term is defined in 27 Pa. C.S. § 6502, of this Environmental Covenant: _____ (name & address information).

4. **Description of Contamination & Remedy**. [***This paragraph needs to be consistent with the Final Report / Remedial Action Completion Report!*** As required by 27 Pa. C.S. § 6504(a)(3) and (a)(7) and as allowed by 27 Pa. C.S. § 6504(b)(6), briefly describe the contamination of the Property before remedy implementation; the remedy/corrective action undertaken; any administrative record for the environmental response project relating to the Environmental Covenant; the Land Recycling and Remediation Standards Act (Act 2) standard(s) attained; and any other important information, including the name and date of the Final Act 2 or Remedial Action Completion Report approved by the Department. Reference Act 2 and UECA definitions as necessary; e.g., "nonresidential property" excludes schools, nursing homes or other residential-style facilities or recreational areas.]

5. **Activity & Use Limitations**. ***[This paragraph needs to be consistent with the Final Report / Remedial Action Completion Report, particularly any postremediation care plan!]*** The Property is subject to the following activity and use limitations, which the then current owner of the Property, and its tenants, agents, employees and other persons under its control, shall abide by: [describe each specific restriction on land use, such as whether the property can be used only for non-residential purposes or whether the groundwater may be used as potable water; describe each obligation, such as groundwater monitoring, maintenance of a fence or cap.]

6. **Notice of Limitations in Future Conveyances**. Each instrument hereafter conveying any interest in the Property subject to this Environmental Covenant shall contain a notice of the activity and use limitations set forth in this Environmental Covenant and shall provide the recorded location of this Environmental Covenant.

7. **Compliance Reporting**. [***This paragraph needs to be consistent with the Final Report / Remedial Action Completion Report!]*** After written request by the Department or by the end of [insert interval for reporting determined to be necessary by the Department; e.g., "every January following the Department's approval of this Environmental Covenant" or "every third January following the Department's approval of this Environmental Covenant"], the then current owner of the Property shall submit, to the Department and any Holder listed in Paragraph 3, written documentation stating whether or not the activity and use limitations in this Environmental Covenant are being abided by. In addition, within 1 month after any of the following events, the then current owner of the Property shall submit, to the Department and any Holder listed in Paragraph 3, written documentation: noncompliance with the activity and use limitations in this

Environmental Covenant; transfer of the Property; changes in use of the Property; or filing of applications for building permits for the Property and any proposals for any site work, if the building or proposed site work will affect the contamination on the Property subject to this Environmental Covenant.

8. **Access by the Department**. In addition to any rights already possessed by the Department, this Environmental Covenant grants to the Department a right of reasonable access of the Property in connection with implementation or enforcement of this Environmental Covenant.

9. **Recording & Proof of Notification**. Within 30 days after the date of the Department's approval of this Environmental Covenant, the [insert entity responsible for filing this document] shall file this Environmental Covenant with the Recorder of Deeds for each County in which the Property is located, and send a file-stamped copy of this Environmental Covenant to the Department within 60 days of recording. Within that time period, the [insert entity responsible for filing this document] also shall send a file-stamped copy to each of the following: [insert each Municipality and County in which the Property is located]; any Holder identified in this Environmental Covenant listed in Paragraph 3; [insert each person holding a recorded interest in the Property]; [insert each person in possession of the Property]; and ____ [insert other persons as required by the Department].

10. **Termination or Modification**.

(a) This Environmental Covenant may only be terminated or modified in accordance with 27 Pa. C.S. §§ 6509 or 6510, or in accordance with this paragraph.

(b) This Environmental Covenant may be amended or terminated as to any portion of the Property that is acquired for use as state highway right-of-way by the Commonwealth provided that: (1) the Department waives the requirements for an environmental covenant and for conversion pursuant to 27 Pa. C.S. §6517 to the same extent that this Environmental Covenant is amended or terminated; (2) the Department determines that termination or modification of this Environmental Covenant will not adversely affect human health or the environment; and (3) the Department provides 30-days advance written notice to the current property owner, each holder, and, as practicable, each person that originally signed the Environmental Covenant or successors in interest to such persons.

[In some circumstances, it may be appropriate for the covenant to be limited to a specific duration or the occurrence of a specific event. If so, specify those conditions that must occur for the covenant to be terminated, and also indicate that the Department must approve, in writing, of the termination. The language in (c) illustrates this option The language in (d) provides an option for not requiring the Grantor's consent.

:

(c) This Environmental Covenant shall terminate upon attainment, in accordance with 35 P.S. §§ 6026. 101 – 6026.908, with an unrestricted use remediation standard for the above-described contamination at the Property. The Department must approve, in writing, of such termination.

(d) In accordance with 27 Pa. C.S. § 6510(a)(3)(i), Grantor hereby waives the right to consent to any amendment or termination of the Environmental Covenant by consent; it being intended that any amendment to or termination of this Environmental Covenant by consent in accordance with this Paragraph requires only the following signatures on the instrument amending or terminating this Environmental Covenant: (i) the Holder at the time of such amendment or termination; (ii) the then current owner of the Property and (iii) the Department.*]*

11. **Department's address**. Communications with the Department regarding this Environmental Covenant shall be sent to: [name, address and title of regional Environmental Cleanup Manager or designee.]

12. **Severability**. The paragraphs of this Environmental Covenant shall be severable and should any part hereof be declared invalid or unenforceable, the remainder shall continue in full force and effect between the parties.

ACKNOWLEDGMENTS by Owner(s) and any Holder(s), in the following form:

SECTION II: ACT 2 REMEDIATION PROCESS

A. Applying Land Recycling Remediation Standards to Your Property

1. Classifying your Site and Considering Options for Remediation

To select a standard for your site, a site assessment is needed to determine site conditions that may require remediation of a release. Characterization of a release includes the identification of specific contaminant concentrations throughout soil and groundwater media, discharges to surface water and air, and any other conditions that may pose a risk to human health and the environment associated with the release. The site characterization may reveal that the remediator needs to interface with other environmental laws and/or Act 2. Under Act 2, the appropriate standard or combination of standards (i.e., background, Statewide health or site-specific) must be determined. The Department will accept notices of intent to remediate (NIRs) for properties on which a release of regulated substances can be documented, or for properties affected by off-property releases of regulated substances for which the remediator is not responsible. The background, Statewide health and site-specific standards may be used at any site. Only certain sites qualify as Special Industrial Areas (SIA).

A person with a property with multiple distinct areas of contamination may submit an NIR for a single area or for multiple individual areas and for one or more than one medium. A distinct area of contamination includes the volume of all media affected by the release causing the contamination. An Act 2 "site" consists of the entire vertical and horizontal area impacted by a release of regulated substance(s). The Act 2 site may cross property boundaries. For example, if soils were contaminated and that contamination migrated to groundwater, both the contaminated soil and groundwater would be part of the distinct area of contamination associated with the release.

In some cases, the Department may agree that characterizing all contaminated media as a distinct area is not practical and may approve a site characterization limited to a single medium. One example of this situation is when a remediator completes a soil media cleanup and an associated groundwater cleanup will take a period of years before attainment can be demonstrated. In this case, the remediator could receive approval of a final report for soils alone (and the associated liability relief), and later when the groundwater is remediated to a point where attainment can be demonstrated, the remediator could submit a separate final report for the groundwater. A second example is the case where a remediator may be approaching multiple areas of concern (AOCs) on the property over a period of years such as multiple soil AOCs, and a groundwater unit which is a combination of the effects of the various soil AOCs. Here the remediator could submit NIRs/final reports for individual soil areas of concern and, at some time in the future when the source areas (all the soil AOCs) have been remediated, submit an NIR for the groundwater unit. The liability protection afforded under Chapter 5 of Act 2 is for contamination from a release identified in the approved final report. Therefore, the more extensive and thorough site characterization is, the more extensive the liability protection. This is true in terms of both size of area included as the site and in the listing of regulated substances which are a part of the site. By example, the lower the censoring level chosen in the site characterization, a larger area and more regulated substances

would likely be included in the site (see Section II.A.4 for an example of applying site characterization to a site).

The Department will specify details of the site in the final report approval letter and attachments, which describe the extent of the liability protection provided under Act 2.

a) Background Standard

A remediator cleaning up a site to the background standard must document that the concentration of any regulated substances remaining are at a level not related to any release of regulated substances at the site. Samples are required both in the area shown to be contaminated by onsite releases (i.e., the site) and in an appropriate background reference area to demonstrate attainment of the background standard. This standard is useful in cases of releases migrating from off-property, for widespread contamination, or naturally occurring conditions.

b) Statewide Health Standard

Chapter 250 establishes Statewide health standards (SHS) for regulated substances in each environmental medium. These standards are referred to as medium-specific concentrations (MSCs), and they must be achieved to demonstrate attainment of the SHS. In addition to demonstrating that a site has attained MSCs based on human health, an ecological screen to demonstrate protection of ecological receptors and a vapor intrusion analysis are part of the SHS.

c) Site-specific Standard

Cleanup levels may be developed which pertain specifically to the unique exposure pathways at a site. This is a more detailed process, both technically and administratively. The human and ecological receptors at the site need to be addressed either through the elimination of the exposure pathways or a risk assessment. A site-specific cleanup also provides an opportunity for public participation.

d) Combination of Standards

A cleanup may be performed by using any combination of the three standards. The remediator may select any one or a combination of standards by regulated substance, by medium of concern, or by distinct area of contamination (see Section II.A.1). Combinations must satisfy all of the requirements of each standard used. For example, in using any combination of standards which includes the site-specific standard, the risk assessment should include only those regulated substances for which site-specific numeric standards are being developed, and for these substances, the cumulative risk requirements of Section 304 of Act 2 (35 P.S. § 6026.304) must be met. Attainment of these site-specific numeric standards must be demonstrated in the final report. In addition, all of the requirements of the site-specific standard, including the reporting requirements, apply. All regulated substances, media, or distinct areas of

contamination meeting another standard (e.g., the SHS) must meet the requirements of that standard. Therefore, in addition to a combination of numerical standards there will be combinations of requirements for reporting, attainment tests, and points of compliance.

e) Special Industrial Areas

A common misconception by users of the land recycling program (LRP) is that there is a separate special industrial area SIA standard. This is not the case. Attainment of one of the three available standards (background, Statewide health or site-specific) can be demonstrated for properties being remediated as SIA sites. However, the focus of the SIA requirements is on characterizing the contamination within the property boundary and addressing immediate, direct or imminent threats to human health and the environment. For further details please refer to Section II.B.4(d)(vii) of this manual.

The SIA designation was created by Act 2 to provide special remediation requirements for a distinct set of properties that were used for industrial activity. SIAs are properties where there is no financially viable responsible party, or where the property is located within an enterprise zone (EZ). EZs are a certain type of distressed property designated by the Department of Community and Economic Development (DCED). Since DCED programs change over time, other property designations may also qualify a property to be an SIA. Remediators are encouraged to consult with DCED to verify that a specific property lies within an established EZ.

The remediator and the reuser afforded these special requirements must demonstrate that he/she did not cause or contribute to releases of regulated substances at the property. The remediator must enter into a Consent Order and Agreement (CO&A) with the Department in order to make use of the SIA designation.

2. Immediate Response

If an immediate hazard exists or is discovered at a site, prompt action is necessary to abate the hazardous condition and prevent future or further release of regulated substances. Leaking tanks or drums, conditions presenting a fire or explosion threat, or a situation involving a threat to human health or the environment warrant a prompt response. Act 2 does not prevent or impede an immediate response to such emergencies. Section 307 of Act 2 (35 P.S. § 6026.307) provides that the provisions under Chapter 3 of the statute, relating to remediation standards and review procedures including SIA cleanups, shall not prevent or impede applicable emergency or interim responses. Final remediation shall comply with that chapter, which will not be prejudiced by the mitigation measures (emergency or interim response) undertaken to that. It is the responsibility of the appropriate person to act in a timely manner to abate immediate threats. The remediator still needs to follow the notification requirements of the Clean Streams Law or Solid Waste Management Act. However, if the final report demonstrating attainment of a standard is submitted within 90 days of the release, the NIR is not required to be filed, and no public notice is required.

3. Notice Requirements and Procedures

a) Notice of Intent to Remediate

Intent to perform a site remediation under the provisions of Act 2 requires municipal, public, and Department notification. The formal process for conducting remediation under Act 2 is initiated with submission of the NIR to the Department. The NIR and instructions are available online at the Land Recycling web page under "Forms and Lists." Submission of the NIR will initiate the notification procedures.

Act 2 provides that any person, firm, corporation, or other entity that proposes or is required to respond to the release of a regulated substance at a site shall comply with public notification requirements except for certain situations defined in Act 2.

The NIR provides basic information on the applicant and the site. The NIR shall include a brief description of the site, ownership information, a listing of the contaminants involved and media affected, proposed remediation (if applicable), and the proposed future use of the site. The NIR may address all of the affected property or may only address those distinct areas of contamination which the remediator chooses to address, which then become sites. Some site characterization is recommended prior to submission of an NIR to obtain sufficient site information to determine the scope of any site contamination and select the remediation standard. Communication with DEP Regional Office staff regarding procedures, assessment, and aspects of remediation is encouraged. The following are the procedures for an NIR:

- Municipal and public notification of the NIR should be submitted at the same time the NIR is submitted to the Department. These notices are accomplished by:
  - Sending a copy of the NIR with an accompanying cover letter to the municipality, or municipalities, where the site is located.
  - Publishing or arranging for the publication of a summary of the NIR in a newspaper of general circulation in the area of the site. This summary should be a legal notice and developed following the model format on the Land Recycling web page under "Forms & Lists."
- At the same time as the submittal of the NIR to the Department, provide the Department with reasonable proof of the public and municipal notification of the NIR. An example of reasonable proof of municipal notification is a copy of the letter mailed to the municipality with the certified mail receipt. A copy of the proposed text of the newspaper notice and expected publication date is an example of proof of public notification. Submit the NIR and reasonable proof of public and

municipal notification to the Department's Environmental Cleanup and Brownfields Program (ECB) office in the region where the site is located. Provide the name and address of a contact person to whom correspondence or communication can be addressed. Provide a copy of the NIR to the owner of the property if the NIR is being prepared and/or submitted by someone other than the property owner. Liability protection is provided to owners of a property. All owners of the properties affected should be included if the area of contamination includes more than one property.

- A 30-day period following submission of the NIR indicating use of the site-specific standard or the SIA process is required by Act 2. The municipality can request to be involved in the development of remediation and reuse plans for the site during this period. The applicant shall inform the municipality of the 30-day comment period when submitting the NIR and should inform the municipality of the provision of Act 2 for requesting a public involvement plan. The newspaper notice shall also provide a statement about the 30-day comment period and the right of a municipality to request involvement in the development of the remediation and reuse plan for the site. The municipality will have received notice prior to publication. The remediator must implement a public involvement plan if the municipality requests involvement in the remediation. The publication date of the NIR notice in the newspaper starts the 30-day comment period. If the model format previously mentioned is used, it will ensure the 30-day comment period and public involvement plan information have been provided. The DEP will not accept reports until after the 30-day comment period. Comments received from the public or a public involvement plan, along with the remediator's responses to the comments, must be submitted with the appropriate final report. A public involvement plan is described below in Section II.A.3(c).

The municipal and public notification requirements of each standard used apply if an NIR is submitted for a combination of standards.

Persons submitting an NIR for background, Statewide health, or a combination of these standards, who later decide to pursue cleanup to a site-specific standard or as an SIA, must re-notice the cleanup according to the appropriate notice provisions.

There are additional public notification requirements for sites being addressed under the One Cleanup Program. If a remediator chooses to enter the One Cleanup Program with coordinated reviews by EPA and DEP, the Memorandum of Agreement (MOA) has established specific site notification requirements. A remediator should submit NIRs to the municipality and a newspaper for publishing. The NIR should include a provision informing the public that any individual may request to receive a copy of the cleanup plan and comment on it prior to its approval and implementation.

Additionally, NIRs submitted for One Cleanup Program sites should include a provision informing the public that any person affected by the release that is the subject of the NIR may request that DEP conduct a site assessment. A DEP official will consider each of these requests and respond as appropriate.

Additional information regarding the One Cleanup Program can be found in Section III.F and in the One Cleanup Program Memorandum of Agreement located on the Land Recycling Program website.

The Department regional ECB office may acknowledge receipt of the NIR and will publish acknowledgment of receipt of the NIR in the *Pennsylvania Bulletin*.

The Department may comment on an NIR if the form is incomplete. An incomplete NIR may not have sufficient information to initiate the Act 2 process. The Department has enforcement authority to require assessment and remediation on sites for which a person does not voluntarily initiate a cleanup under Act 2.

Public notification of submission of the NIR to the Department, the municipality, and the public via the newspaper notice, and publication in the *Pennsylvania Bulletin*, are not required for background or Statewide health standard remediations if the final report demonstrating attainment of the standard is submitted within 90 days of the release.

b) Notice of Proposal for Nonuse Aquifer Determination

Any time a person is proposing to the Department that a site be eligible for a Nonuse Aquifer Determination, notice must be given to the associated municipalities and local water suppliers servicing that area. The notice is similar to that of an NIR in that it is a letter format and identifies the associated "who" and "where" of the proposal. In addition, a copy of the proposal sent to the Department for approval should be attached to these notice letters. Under general conditions, the municipalities and community water suppliers will have 45 days to review this material and, if desired, provide the Department with any information relative to the nonuse aquifer determination requirements specified in Section 250.303(c) of the regulations. These conditions will be those upon which the Department will base its approval decision. In the specific case where a municipality has in place an ordinance meeting the performance criteria of this Technical Guidance Manual (TGM), Section III.E.3 (relating to institutional vs. engineering controls), the 45-day review period may be waived.

c) Public Involvement Plan

All remediators conducting cleanups are encouraged to develop programs with a proactive approach to involving communities in their plans. Remediators selecting the site-specific standard or pursuing remediation as an SIA must provide an NIR to the Department and the municipality, and to the public via notice in a newspaper serving the general area of the site. A 30-day comment period is to be included as part of the initial notice to solicit comments on whether the municipality wishes to be involved in the development of the cleanup and

reuse plans for the site. The remediator of the property shall prepare a public involvement plan which meets the provisions of Section 304(o) of Act 2 if the municipality requests involvement during the comment period (35 P.S. § 6026.304(o)). If requested by a municipality, the remediator is encouraged to collaborate with the municipality in the development of the public involvement plan. This plan shall propose measures to involve the public in the development and review of the remedial investigation report, risk assessment report, cleanup plan, and final report for site-specific standard remediations, and the baseline remedial investigation for SIAs. Public involvement measures may include:

- Development of a proactive community information and consultation program that includes doorstep notice of relevant activities.
- Public meetings located within the county where the site is located.
- Roundtable discussions.
- Public access for document review and discussion, and designation of a single contact person to address questions from the community. Such access should be at locations adjacent to primary highways for the convenience of the public wishing to review the material.
- Formation of a community-based group to solicit suggestions and comments.
- Where needed, retention of a qualified independent third party to facilitate meetings and discussions and to perform mediation services.

The remediator can use these or other appropriate methods, such as a website or social media, to ensure the community has ample notice of intended remedial/reuse actions and the appropriate public concerns are properly addressed. The remediator must submit a copy of the public involvement plan to the Department as outlined in Section 250.6(d) of the regulations. DEP does not approve or disapprove public involvement plans. The reports and plans submitted to the Department must include the comments received from the public and the municipality as well as responses to those comments. The Department will consider these comments as part of its review of the plans and reports.

d) Remediation Report Notification Requirements

i) Background and Statewide Health Standards

When a final report is submitted under the background and Statewide health standards the remediator should provide two copies of the final report to the Department's ECB Program regional office where the site is located. One should be a paper copy and the other can be submitted in another format (CD, flash drive, etc.). A complete submission consists of the report, a Transmittal Sheet, a printout of the online final report summary, the checklist (optional), and the appropriate fee. The

Transmittal Sheet and checklist are available on the Land Recycling website under "Forms and Lists." The name and address of a contact person to whom correspondence or communication can be addressed shall be provided. The Department will acknowledge receipt of the final report. The remediator shall provide municipal and public notification that a final report has been submitted when the final report is submitted to the Department. This notification is accomplished by:

- Sending a notice to the municipality that a final report has been submitted to the Department. (A model format for this notification is available on the Land Recycling website under "Forms and Lists.")

- Providing a notice of submission of the final report to a newspaper of general circulation in the area of the site. This notice shall be a legal notice and developed following the model format (available on the website) or other appropriate format provided by the newspaper and provide the required information.

- Providing the Department with reasonable proof of the public and municipal notification by submitting a copy of the proposed text of the newspaper notice and the anticipated publication date or a photocopy of the published notification showing the publication date. Proof of municipal notification of submission of the final report may be accomplished by submitting a copy of the certified mail receipt and cover letter of the municipal notice to the Department.

The Department has a 60-day review period for the final report and shall notify the remediator of deficiencies. It is the intent of the Department to notify the remediator of both approvals and deficiencies of the final report. The final report shall be deemed approved if the Department does not respond within 60 days.

Other reports that fall outside of the scope of the typical reporting guidelines are reviewed on a case-by-case basis and timeframes for such reviews will vary based on the complexity of the site.

The Department's regional ECB office will publish acknowledgment of receipt of the final report in the *Pennsylvania Bulletin*.

Public notification of submission of the final report to the Department, the municipality, the public via the newspaper notice, and publication in the *Pennsylvania Bulletin* is not required for background or Statewide health standard remediations if the final report demonstrating attainment of the standard is submitted within 90 days of the release.

ii) Site-specific Standard

Under the site-specific standard, when a remedial investigation report, risk assessment report, cleanup plan, or a final report is submitted, the remediator should provide two copies of the document to the Department's ECB Program Regional Office where the site is located. One should be a paper copy, and the other can be submitted in another format (CD, flash drive, etc.). A complete submission consists of the document, a Transmittal Sheet, the checklist (optional) and the appropriate fee(s). The Transmittal Sheet and checklist are available on the Land Recycling website under "Forms and Lists." In addition, the submission of a final report should include a printout of the online final report summary. The name and address of a contact person to whom correspondence or communication can be addressed shall be provided. The Department will acknowledge receipt of the submission. The remediator shall provide municipal and public notification of the submission when the plan and/or reports are submitted to the Department. This notification is accomplished by:

- Sending a notice by certified mail to the municipality that a specific plan and/or report has been submitted to the Department. (A model format for this notification is available on the Land Recycling website under "Forms and Lists.")

- Providing a notice summarizing the findings and recommendations of the plan or report, along with the comments and responses, to a newspaper of general circulation in the area of the site. This notice shall be a legal notice or other appropriate format provided by the newspaper and provide the required information.

- Providing the Department with reasonable proof of the public and municipal notification by submitting a copy of the proposed text of the newspaper notice and the anticipated publication date or a photocopy of the published notification showing the publication date. Proof of municipal notification of submission of the final report may be accomplished by submitting a copy of the certified mail receipt and cover letter of the municipal notice to the Department.

Remedial investigation reports, cleanup plans, and risk assessment reports may be submitted together or separately. It is recommended that the risk assessment be submitted individually because risk assessment reports are considered stand-alone reports with separate fees and are reviewed independently of other reports.

The Department has a 90-day review period for the plan and/or report and shall notify the remediator of deficiencies. It is the intent of the Department to notify the remediator of both approvals and deficiencies of

the final report. The plan and/or report shall be deemed approved if the Department does not respond within 90 days.

Other reports that fall outside the scope of the typical reporting guidelines are reviewed on a case-by-case basis, and timeframes for such reviews will vary based on the complexity of the site.

iii) Special Industrial Areas

Municipal and public notification is required for submission of an NIR to the Department, but it is not required for submission of a baseline environmental report.

e) Fees

The Department is required to collect fees to cover some of the costs of the LRP. Section 703 of Act 2 specifies the appropriate fees involved for submission of plans and reports (35 P.S. § 6026.703). The regulations provide further specification on fees (25 Pa. Code § 250.7).

A fee of $250 is required for the review of final reports for the background and Statewide health standards, and $250 for each remedial investigation, risk assessment report, and cleanup plan for the site-specific standard. A fee of $500 is required at the time of submission of the final report for site-specific standard remediations. No fee is required for submission of the work plan or baseline environmental report required for SIA remediation. It is important to note that submitting a combination of reports under the site-specific standard requires a fee for EACH report submitted. For example, if one report containing a remedial investigation/risk assessment/cleanup plan for a site undergoing a site-specific cleanup is submitted to the Department, then $750 is required to be submitted with the report. A final report submitted under a combination of cleanup standards should be accompanied with a fee representing the higher of the two standards' final report fee.

Resubmission of any of the above required plans and reports will require payment of the above fee upon resubmission. The Department may disapprove a plan or report that does not have the appropriate fee.

Checks are to be made payable to the **Commonwealth of Pennsylvania**.

A *Transmittal Sheet for Plan/Report Submission* is available for remitting the appropriate fee with the submittal and should be used with all plan/report submissions to the Department. This form may be obtained from the LRP web site under "Forms and Lists," or a copy may be requested from the Department's Regional office where the site is located or from the Department's Central office.

4. Site Characterization

a) Importance of Site Characterization Step

Site characterization under Act 2 is a description of contaminated media, including geology and chemical and physical characteristics, that affect movement of regulated substances in environmental media. Site characterization is the process for determining the site under Act 2; i.e., the volume of contaminated media resulting from an environmental release of regulated substances within which attainment of one or a combination of standards will be demonstrated. The site is, in turn, the basis for liability protection under Chapter 5 of Act 2 when the final report is approved. In brief, the liability protection is only as good as the site characterization.

The site characterization activities conducted must result in a thorough investigation which meets the requirements of Pa. Code § 250.204. **A complete and accurate site characterization, including fate and transport analysis, and its documentation in the final report is very important, as it is the basis for making remediation decisions and is used later in identifying the appropriate area for demonstrating attainment. Except for sites involving the excavation option for petroleum-contaminated soil (see 25 Pa. Code § 250.707(b)(1)(iii)), without a proper site characterization, attainment requirements cannot be met and the final report will be disapproved by the Department.**

A remediator must keep in mind the definition of a site under Act 2. As defined in Act 2, a site is "[t]he extent of contamination originating within the property boundaries and all areas in close proximity to the contamination necessary for the implementation of remediation activities to be conducted under the act" (35 P.S. § 6026.103). Thus, a site often does not coincide with a property. A site may occupy several properties, and, conversely, a property may contain more than one site. In this manual, whenever the term "site" is used in connection with the LRP, it is used strictly in the sense as defined in Act 2.

DEP Regional Office staff are a valuable resource and want to assist as needed in evaluating site characterization information. Although not required, working with the Department can help to facilitate approval of the submitted reports. Remediators should always feel free to contact the Department's Regional ECB Program staff when there are questions about site characterization requirements of a property under the LRP.

b) Scope of Characterization

The scope of the site characterization should be designed to help the remediator select an appropriate remedy that will meet the attainment requirements of the selected Act 2 standard. The requirements that a site characterization must meet are described in the regulations at 25 Pa. Code § 250.204. During this phase of the application of Act 2, the remediator should evaluate other applicable regulatory requirements (see Section V of this manual), since information required by other programs may be best collected during the site characterization

phase. The reporting requirements for the selected standard (background, Statewide health or site-specific in Act 2 and Chapter 250 of the regulations) must be met by the person conducting the cleanup. Section II of this TGM describes in detail the reporting requirements for each of the standards available under Act 2. The procedures, documents, and required fees for each standard are summarized in Section II.A.3 (Notice Requirements and Procedures).

Characterization of sites which may require remediation begins with an evaluation of any existing historical information about the release that identifies specific regulated substances. The data objectives of the site characterization will differ somewhat depending on whether soil or groundwater is being investigated. Depending on the size and complexity of the site, the investigation portion of the site characterization is typically an iterative process which expands and builds as the information is gathered (see Figure II-1).

i) Soils

Soils must be characterized horizontally and vertically to concentrations below the selected numeric standards, or to where it can be demonstrated that the pathway elimination measure is adequate to protect human health and the environment. This ensures that all soils containing regulated substances at or above the selected numeric standards have been adequately characterized to support a fate and transport analysis which shows where the contamination is currently located and those areas to which it is moving. The remediator determines the concentration level for characterization beyond the minimal level stated above. The remediator must state what factors were used in determining the level used to define the site boundaries.

A thorough site characterization for soil should be able to provide the following information:

- The types of regulated substances associated with a release that are present, their concentrations, and the spatial variation in concentration of the regulated substances both horizontally and vertically.

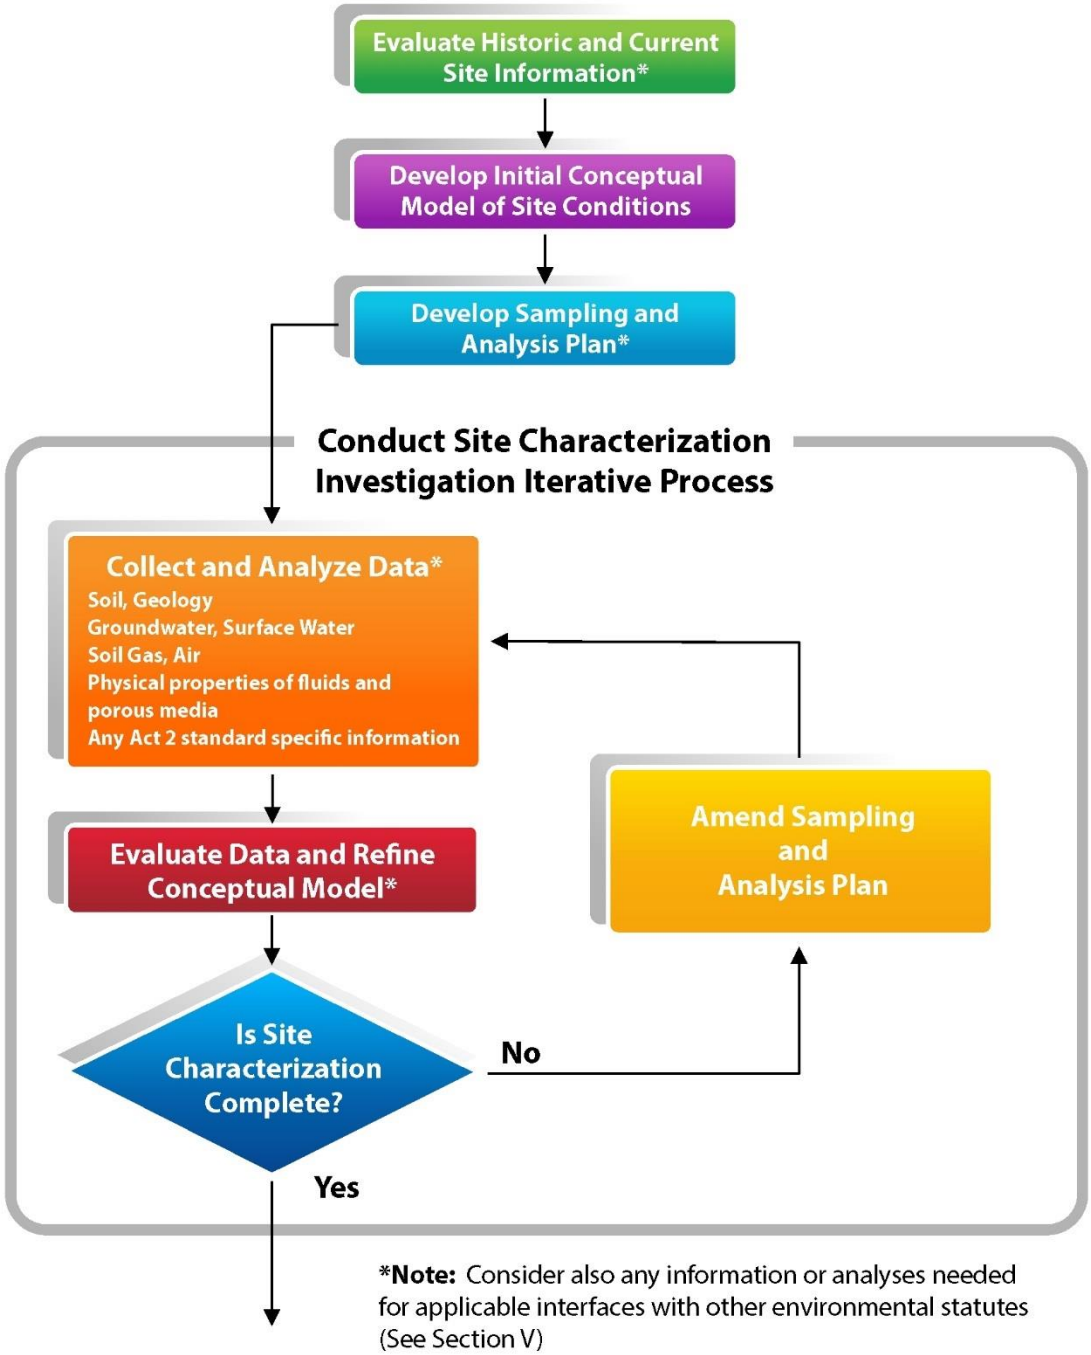
- The physical characteristics of the soil in which the regulated substances associated with a release are present and through which they may be moving. These include the soil type (texture), dry bulk density, permeability, organic carbon content, porosity, and moisture content. Documentation of these properties and any significant variability over the site may be very important later in developing a fate and transport analysis.

Soil characterization samples should be collected from the areas with anticipated highest levels of contamination (i.e., biased sampling). This sampling method identifies the areas of concern (AOC) and helps to

determine the applicability of any proposed remedial action or soil handling and disposal requirements during remediation.

It is important to remember that liability relief is afforded by Act 2 only for the distinct areas of contamination identified and evaluated in reports submitted to and approved by the Department. This is explained in Section 501(a) of Act 2. Thus, liability relief applies to specific releases regardless of when the release occurred or when the data associated with that release was collected. Liability relief is not provided for the entire property unless the entire property is identified as the site. If an additional release has occurred at the site, liability relief is not provided for that release until an Act 2 standard is attained for contamination associated with that specific release. Historical data (i.e., data more than two years old) can be used during site characterization if there is no reasonable expectation that the site conditions associated with the release being investigated have changed (e.g., changes in property use resulting in changes in exposure). Historical data should be provided in the final report as required by 25 Pa. Code § 250.204(c).

Figure II-1: Site Characterization Decision Tree



Note: Figure must be used in conjunction with the text. Reference Sections II.A.4 and IV.

ii) Groundwater

If groundwater is known to be impacted by a release based on knowledge of the site or as a result of soil sampling, a similar process as that used for soils to determine the extent of the release into groundwater may be employed based on knowledge of the site, groundwater monitoring, and fate and transport analysis. A common mistake is to take a limited set of groundwater measurements from a single sampling event, and if the concentrations are below the SHS, conclude that no further Act 2 work is needed. This is not true. Proper characterization requires more than one round of sampling [25 Pa. Code § 250.204(e)]. For further guidance, see Section III.B.

Where groundwater is a medium of concern, the following information at a minimum should be provided by a thorough site characterization:

- The direction of groundwater flow.
- The hydraulic gradient.
- The permeability of the aquifer material(s) through which the groundwater moves.
- The porosity of the aquifer.
- The types of regulated substances present, their concentrations, and the spatial variation in concentration of the regulated substances both horizontally and vertically.

This information is not only necessary to describe and evaluate conditions at the site, but also is often vital to fate and transport analysis, especially when it requires a quantitative approach.

Fate and transport analysis often is an important part of site characterization and demonstration of attainment and is frequently required under all three Act 2 standards. See Section III.A for guidance for conducting fate and transport analyses.

Historic groundwater monitoring data can be useful for establishing trends and under certain circumstances, delineating groundwater COCs. Remediators can use historic data for identifying trends at sites that are not reasonably expected to have changes in site conditions associated with the release being investigated (e.g., natural attenuation or degradation). Historic groundwater data can be used to delineate contaminants from a specific release provided the groundwater quality has remained consistent and no product degradation has occurred. However, be careful in the use of groundwater data collected prior to remediation for attainment purposes. This data may over estimate concentrations of COCs that have

degraded or underestimate the concentrations of daughter products generated by degradation.

iii) Sediment

Act 2 allows for liability relief to be granted for regulated substances in sediment. Specifically, Section 302(b)(1) of Act 2 allows for demonstration of attainment of media of concern which may include sediment.

A remediator may demonstrate attainment of the background standard as described in Subchapter B of the Chapter 250 regulations, and in 25 Pa. Code § 250.707(a). The point of compliance for sediment is not specifically discussed in the regulations but remediators are generally expected to demonstrate attainment throughout the area of the sediment that has become contaminated due to releases on the property.

The LRP has not established numeric cleanup standards for sediments. However, sediment is sometimes only a concern to ecological receptors in which case remediators can address sediment under the SHS through the application of the ecological screening process described in Pa. Code § 250.311. The numeric soil standards published in the regulations cannot be used for sediments, as the exposure assumptions used to develop those values are not applicable to sediments. For remediations under the site-specific standard, the site-specific ecological risk assessment process should be used to demonstrate attainment for sediment.

iv) Conceptual Site Model Including Soil and Groundwater

A complete and comprehensive site characterization will enable the development of a conceptual site model (CSM). The CSM is a representation of the site environmental system and the processes that control the transport and movement of regulated substances through the environmental media and how they interact. The CSM assists in organizing the site investigation by identifying uncertainties and data gaps and focusing data collection efforts. Information from the CSM can also be used in the development of a vapor intrusion analysis or a risk assessment.

The CSM can be depicted in different ways such as written text, a graphic illustration, or a flow chart. The investigation portion of the site characterization is typically an iterative process which expands and builds as information is gathered. Consequentially, the CSM is a dynamic tool to be updated as new information becomes available during site characterization.

The level of complexity of the CSM and the level of detail needed is directly related to the level of complexity of the site, the selected remediation standard and the applicable media of concern. Less complex

sites need only a basic CSM to illustrate contaminant migration pathways, exposure mechanisms and potential receptors. More complicated sites will most likely need a CSM with a higher level of detail to describe all the different routes of exposure through multiple environmental media to various potential receptors.

EPA, American Society for Testing and Materials (ASTM), and Interstate Technology & Regulatory Council (ITRC) all provide additional guidance that may be used when conducting the site characterization investigation and developing the CSM. Appendix A, Groundwater Monitoring Guidance, is also an appropriate source of information. Figure II-2 below provides an example of a graphical CSM. Figure II-3 provides an example CSM of a wood treatment facility in a tabular format.

v) Conceptual Site Model Example

A release of 1,100 gallons of jet fuel to the ground surface at a regional airport resulted from an overfill of an above ground storage tank. A total of 2,500 cubic yards of contaminated soil was excavated. Confirmatory soil samples were collected from the excavation pit and monitoring wells were installed to delineate groundwater impacts. Soil and groundwater samples revealed detections of benzene, ethylbenzene, cumene, naphthalene, toluene, and xylenes. Nine groundwater sampling events were performed over a three-year period. Groundwater monitoring results indicated that the plume had stabilized and groundwater concentrations had decreased below the SHS groundwater MSCs. However, confirmatory soil samples showed that all of these constituents, except ethylbenzene, were detected at concentrations below the SHS MSCs. Therefore, all but ethylbenzene could be carried through the SHS process.

All soil and groundwater detections were compared to the SHS vapor intrusion screening values to delineate a potential vapor intrusion source. Since this was a petroleum release and concentrations exceeding the vapor intrusion screening values were more than 30 horizontal feet from any building and no future buildings were planned in this area, no additional vapor intrusion analysis was needed (see Section IV for vapor intrusion screening values and a discussion of the use of proximity distances).

An evaluation of potentially complete exposure pathways was performed by going through the SHS ecological screen process described in 25 Pa. Code § 250.311. Since jet fuel was the only substance released at the site, it was determined that no additional ecological evaluation was needed for the constituents being evaluated under the SHS (see Section II.B.2(e) for additional information on the SHS ecological screen process).

The ethylbenzene concentrations in soil that exceeded the MSC were the only remaining issue, so the remediator decided that this contaminant would be evaluated using the site-specific standard. The remediator performed a satisfactory receptor evaluation in their CSM and identified

airport workers, construction workers, utility workers, and travelers all as individual receptors with different exposure parameters.

Figure II-2: Graphic Example of Conceptual Site Model

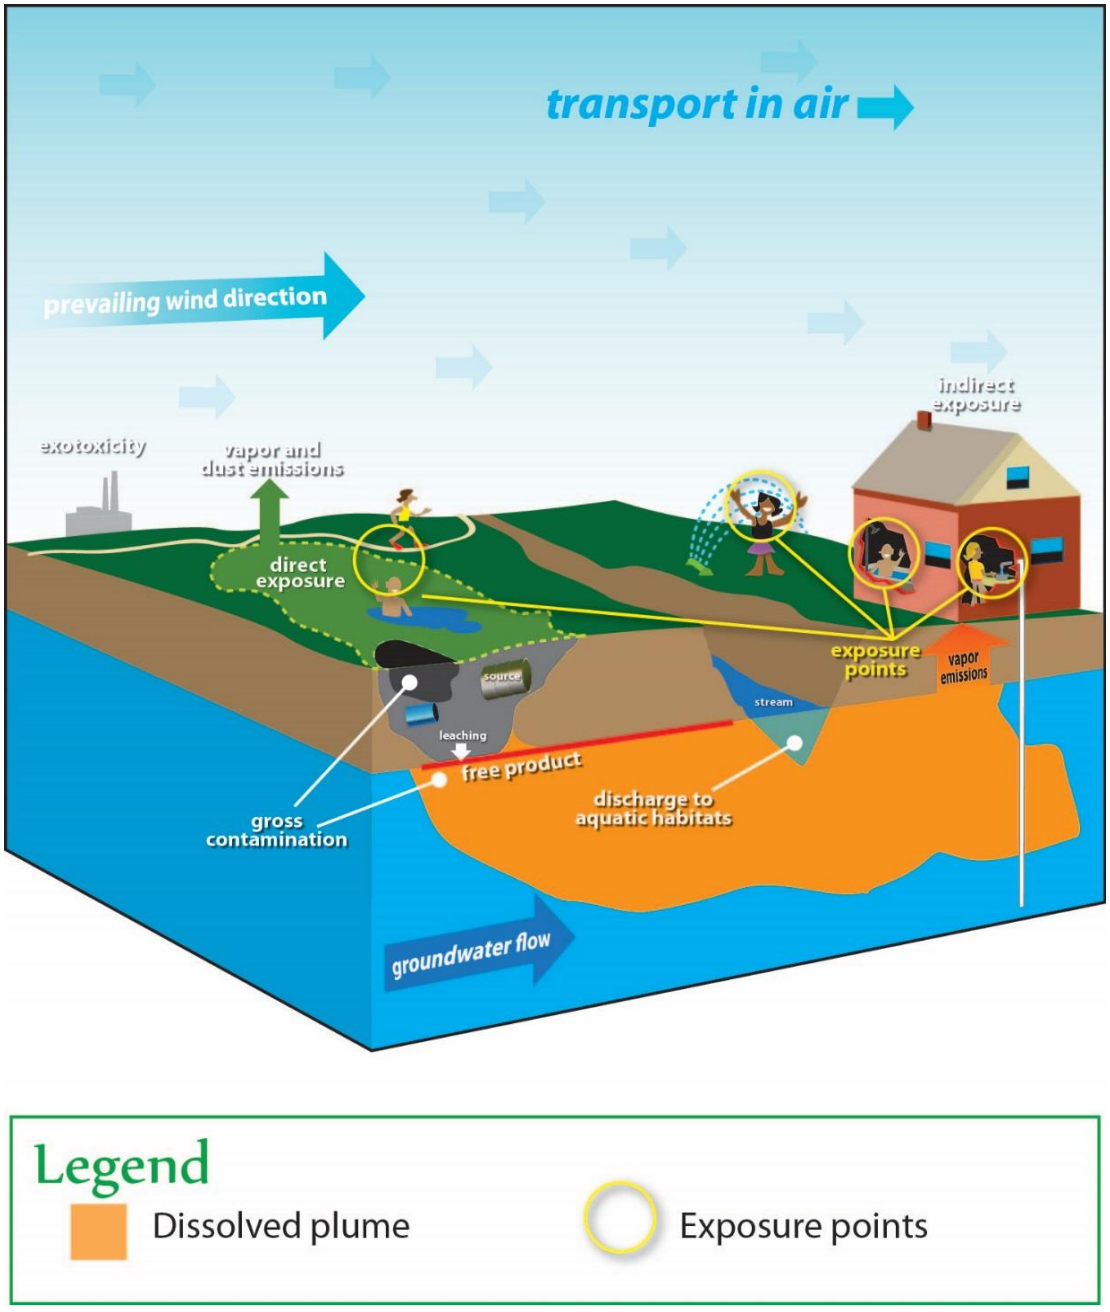


Figure II-3: Flow Chart Example of Conceptual Site Model

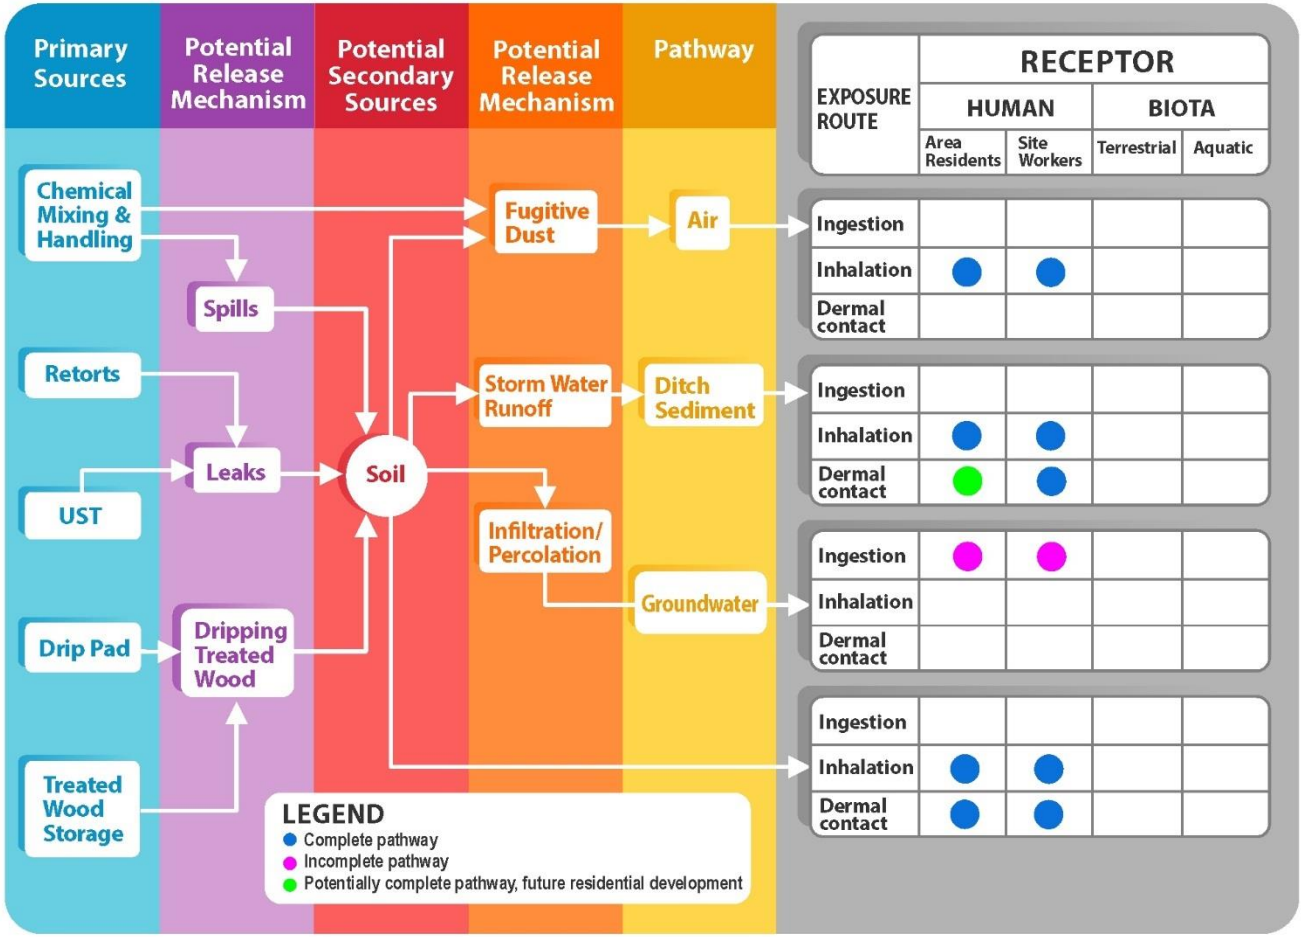


Source: ITRC, Decision Making at Contaminated Sites, January 2015

Note: Figure must be used in conjunction with the text. Reference Section II.A.4.

Although the ecological screen process under the SHS was performed for the constituents being evaluated under the SHS, a site-specific ecological risk assessment is still required for constituents being evaluated under the site-specific standard (see Section III.I for additional information on the site-specific ecological risk assessment process). Thus, an ecological receptor evaluation was performed using the Pennsylvania Natural Diversity Index (PNDI) online search tool to identify any habitats or species of concern that may have been impacted by the release. The results of the PNDI search showed that there were no habitats or species of concern identified as potentially impacted by the release at the site.

This is an example of a complete CSM because the remediator accomplished the following characterization goals:

- Delineation of soil contamination down to SHS MSCs and to SHS vapor intrusion screening values.

- Delineation of groundwater contamination down to SHS MSCs and to SHS vapor intrusion screening values. The delineation of groundwater included a robust data set with over four consecutive quarters of groundwater monitoring, which accounted for any potential seasonal variations (while four consecutive quarters of groundwater data are not required for characterization, it helps greatly in evaluating seasonality concerns and with generating a dataset to be used for groundwater modeling, if necessary).

- The vapor intrusion pathway was adequately evaluated by identifying the potential vapor intrusion source and using proximity distances to evaluate exposure.

- Exposure pathways for ecological receptors were effectively evaluated for both the SHS process and the site-specific standard requirements.

- All potential human health receptors and exposure pathway were adequately evaluated, including the pathways that were incomplete.

By fully delineating all impacted environmental media and by performing a complete receptor analysis, the remediator could effectively evaluate all the site environmental systems and the processes that control the transport and movement of regulated substances through the environmental media and how they interact.

c) Applying Site Characterization to an Act 2 NIR – Example

A characterization of soil contamination is shown in Figure II-4. This example considers a large property with several smaller environmental releases. There are two general areas where environmental releases occurred. The remediator has

initial results which suggest these two areas of concern for further study. Furthermore, the remediator of this property wished to obtain Act 2 liability relief for this release so that the property can be more easily sold. With this objective in mind, the remediator plans a site characterization and weighs options. The following are considerations that must be made.

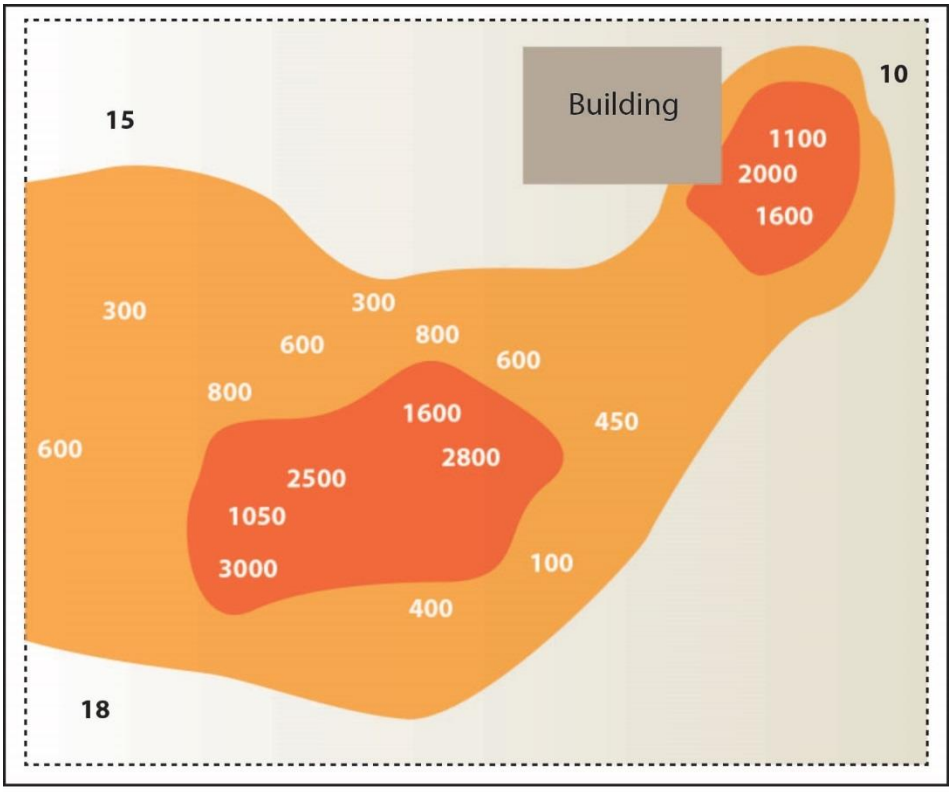
In addition to factors that will help to characterize the hot spots, the remediator must consider, first in designing further investigations and later in finalizing the site characterization, what is the concentration of regulated substance(s) in soil that will represent the boundary of the site. It is technically more difficult and more expensive to define the extent of the contamination to lower concentrations than it would be to define hot spots. However, the Act 2 liability protection only applies to the site, and if the extent of the site is very limited, so too is the liability protection.

To apply attainment in soils, the remediator must at a minimum define the volume which exceeds the selected standard (25 Pa. Code § 250.703(b)). Sampling beyond the initial phase indicates that two areas exceed the SHS MSCs. The remediator reasons that, by choosing the boundary of the site to be concentrations much lower than the standard, the area of the liability protection is increased. The remediator considers 25 percent of the standard, 10 percent of the standard, and the Practical Quantitation Limit (PQL) of the substance(s) as resolution options. The extra cost of characterization allows the remediator to maximize the site area (and consequently the liability protection) by choosing the PQL and applying it across the entire property. Within this site area, the remediator also characterizes factors of the media and regulated substance(s) which affect movement (see Section III.A, Fate and Transport Analysis). Another remediator may have made a different choice and ended up with several smaller sites with liability protection.

In considering the definition of the site in groundwater (i.e., the plume), some phase of the assessment must determine if the contamination extends beyond the property boundary at levels exceeding the selected standard (25 Pa. Code § 250.704). If the determination is that levels off the property do not exceed the standard, then the remediator determines that the standard can be attained at the Point of Compliance (POC). Figure II-5 illustrates this situation.

If the contamination extends beyond the property boundary at levels exceeding the selected standard, then the boundary of the site in groundwater must include the contamination exceeding the appropriately selected standard off the property. Figure II-6 illustrates this situation. A remediator must remember that if the plume exists on both residential and nonresidential properties, then different numeric standards would apply at those properties in most cases. Background values may also be determined (25 Pa. Code § 250.707(a)(2)).

Figure II-4: Site Characterization of Soil Contamination



Legend

800 Soil sample analytical result (mg/kg)

Delineation of soil concentrations >practical quantitation limit

Delineation of soil concentrations >MSC concentrations
MSC = 1,000 mg/kg
PQL = 20 mg/kg

Property boundary

Figure II-5: Site Characterization of Groundwater Contamination
No Off-Property Groundwater Concentrations > MSC

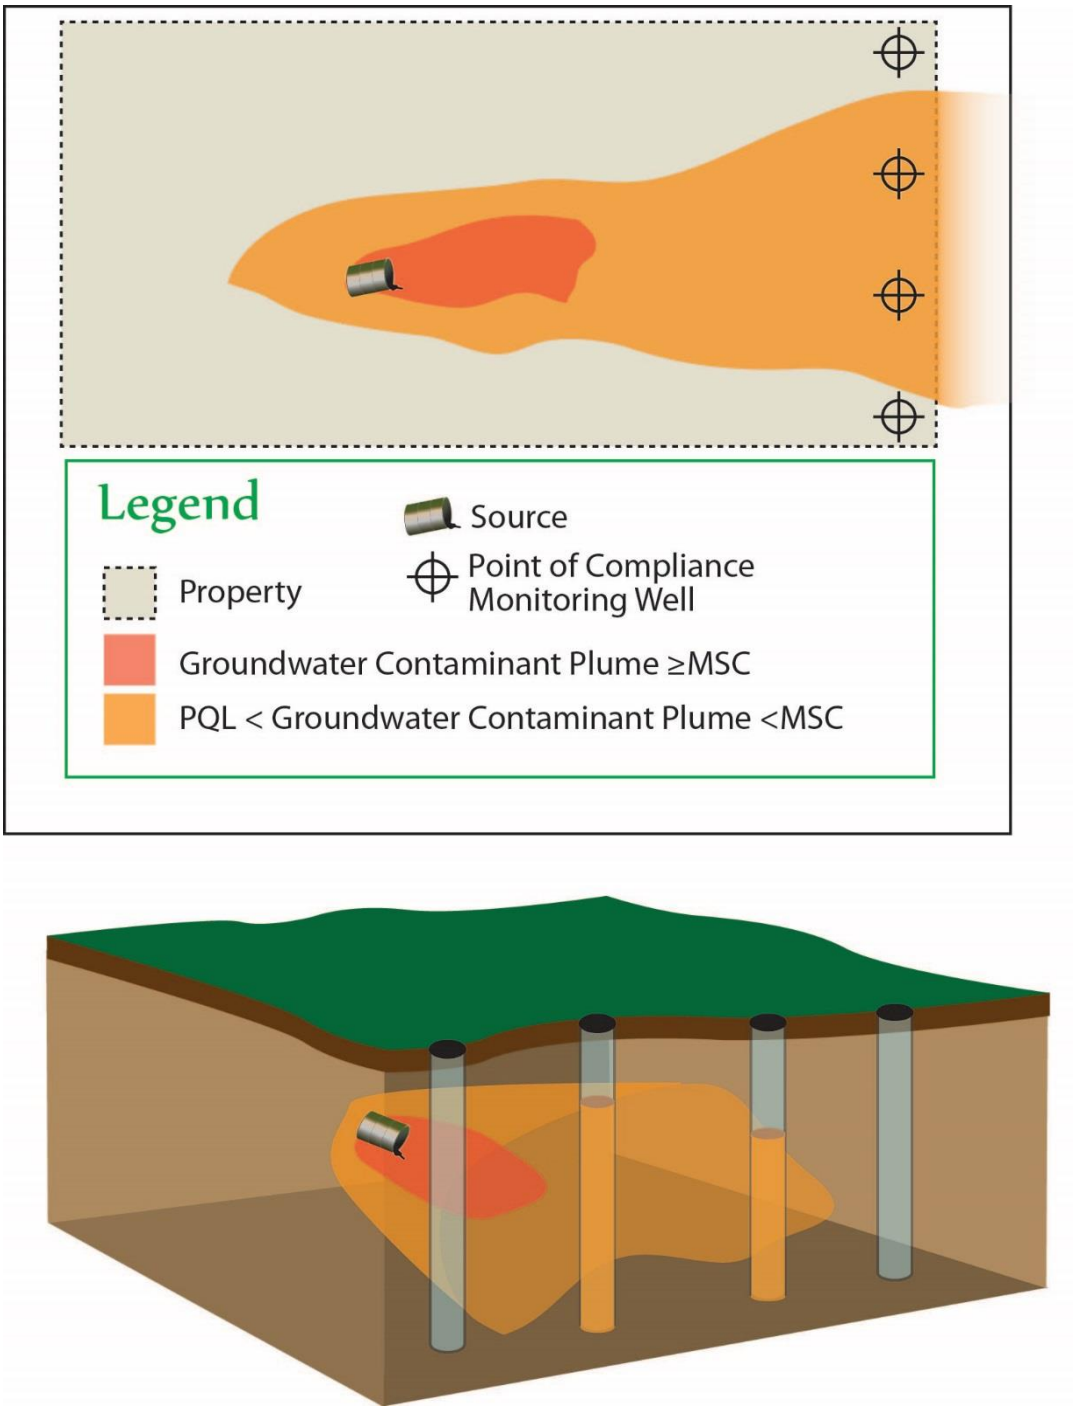


Figure II-6: Site Characterization of Groundwater Contamination Under Statewide Health Standard

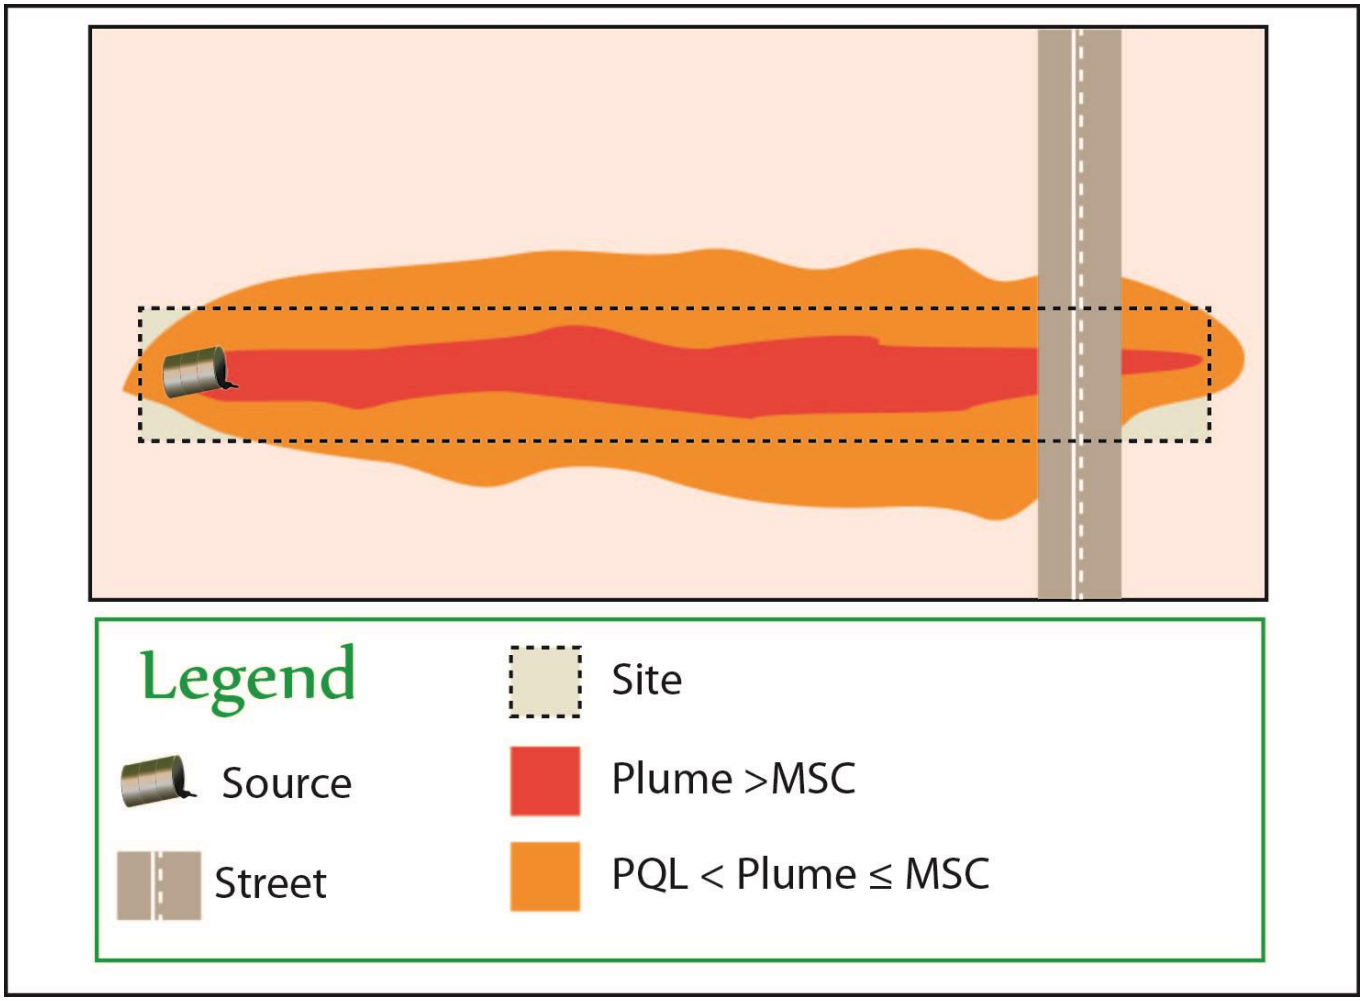

Two or more rounds of sampling and analysis must be performed once the extent of contamination in groundwater is established utilizing properly constructed monitoring wells (25 Pa. Code § 250.204(e)).

If no groundwater remediation is needed (e.g., both rounds of sampling are below the selected standard), the remediator may use the site characterization sampling as part of the required attainment demonstration. The Department may approve a reduction in the number of quarters of sampling needed to demonstrate attainment provided there is appropriate justification under 25 Pa. Code § 250.704(d).

B. Remediation Standards

1. Background Standard

a) Introduction

This chapter presents procedures to be used in assessing site contamination and demonstrating attainment of the background standard. Use of this guidance and data submission formats should simplify reporting on the site and reduce delays in obtaining final report approval by the Department. This chapter is designed to help those involved understand and meet the requirement of the background standard under Act 2 and the regulations in 25 Pa. Code Chapter 250. Environmental Cleanup and Brownfields Program staff in the Regional Offices are a valuable resource and will assist in answering questions on the background standard.

Background is the concentration of a regulated substance that is present at a site, but is not related to the release of regulated substances at the property. Attainment of the background standard for a regulated substance may be demonstrated by an analysis of environmental media within and around the site (35 P.S. § 6026.302). Establishing the background concentration is discussed in Subsection II.B.1(d) of this manual. Subchapter B under Chapter 250 of the regulations also discusses the background standard requirements.

The background standard may result in higher than health-based level contamination (e.g. SHS MSCs) moving onto the property from an adjacent property or from constituents which are naturally occurring. Background quality is the concentration of substances which are unrelated to the release on the site.

In order to demonstrate compliance with the background standard, remediators should demonstrate that onsite media do not exceed the background standard for a regulated substance(s) by statistically developing representative contaminant concentrations through onsite and background reference samples of the environmental media. Subchapter G under Chapter 250 of the regulations establishes statistical tests recognized by the Department for the demonstration of attainment. Background statistical attainment requirements are in 25 Pa. Code § 250.707(a)(1) for background soils and Pa. Code § 250.707(a)(2) or (3) for background groundwater. Demonstration of attainment for background is discussed in Subsection II.B.1.e.vi of this manual.

Reporting the completion of a remediation to the Department requires a final report that contains a detailed description of the process taken to reach the background standard and the reasoning for choosing media for testing. Section 250.204 of the regulations discusses the requirements for a final report. Section II.B.1(e) of this manual also contains a discussion on the final report requirements for the background standard. Summaries of sampling methodology and analytical results showing attainment should be included with the report 35 P.S. § 6026.302(b)(2).

Institutional controls such as fencing and future land use restrictions on a site may not be used to attain the background standard. Institutional controls may be used to maintain the background standard after remediation occurs 25 P.S. § 6026.302(b)(4).

If the initial remediation chosen by the remediator fails to attain the background standard, the remediator may choose instead to meet the Statewide health or site-specific standards 35 P.S. § 6026.302(c). Sites attaining and demonstrating compliance with the background standard are not required to meet the deed acknowledgment requirements of the Solid Waste Management Act (SWMA) or the Hazardous Site Cleanup Act (HSCA) or the Uniform Environmental Covenants Act (UECA). An existing acknowledgment contained in a deed prior to demonstrating compliance with the background standard may be removed.

b) Process Checklist for the Background Standard

☐ Review the historic and current information and present use of regulated substances at the property.

☐ Begin the site investigation/characterization and gather information about the area on and around the property.

☐ As an option, begin using the completeness list (see LRP website) to help verify that all requirements have been met.

☐ Determine if property/site is affected by regulated substances not originating from the property.

For the groundwater background concentration, establish if it is naturally occurring/area-wide or from an upgradient source (see 25 Pa. Code § 250.707).

☐ For the soils background concentration, establish if it is a naturally occurring or area-wide problem. The Department has not established background concentrations for naturally occurring substances as they may vary considerably across the Commonwealth. Geochemical references are available for certain rock and soil types in Pennsylvania and should be cited as appropriate. Background concentrations should be determined on a site-by-site basis.

☐ If using the naturally occurring/area-wide background distinction, request in writing and receive back in writing the Department's approval that the site is indeed in an area of widespread contamination for the regulated substance on your property/site before submitting the NIR (see 25 Pa. Code § 250.707(a)(3)(i)).

☐ Continue with the site characterization and required activities needed to complete the final report (see 25 Pa. Code § 250.204).

☐ Submit an NIR for the background standard. Also, send a notice to the municipality, publish a notice in a local newspaper, and attach reasonable proof of required notices for inclusion with the final report to the Department 35 P.S. § 6026.302(e)(1). Procedures for submittal of notifications are contained in Section II.A.3 of this manual. Links to sample forms are located on the LRP website.

☐ Remediate the site to the background standard.

☐ Demonstrate attainment of the background standard pursuant to 25 Pa. Code § 250.203.

☐ Calculate mass of contaminants remediated using the procedure in Section III.D of this manual.

☐ Complete the final report summary and submit electronically as instructed on the LRP website.

☐ Prepare and submit the final report, along with the optional completeness list (if used) to the appropriate DEP Regional Office. See Section 302(b)(2) of Act 2, 35 P.S. § 6026.302(b)(2), 25 Pa. Code § 250.204, and Section II.B.1(e) of this manual.

☐ If the final report is approved, the liability protection set forth in Chapter 5 of Act 2 automatically applies.

☐ If engineering controls were used and postremediation care is required to maintain the standard, continue with the postremediation care program detailed in the final report. Postremediation care would not normally be used for the background standard.

☐ When the background standard can be maintained without engineering controls operating, document this to the Department and receive approval to terminate the postremediation care program.

☐ Submit an environmental covenant, if applicable, to the Department.

c) Point of Compliance (POC) for the Background Standard

For the background standard, the POC for groundwater is throughout the area of contamination (plume) both from the offsite (upgradient) release that migrates onto the property and another release within the property, including areas to which the onsite release has migrated off the property above the background standard as determined by the site characterization (see Figures II-7 and II-8). This differs from the groundwater POC for the Statewide health and site-specific standards. (See 25 Pa. Code § 250.203(a)).

For a property located within areawide contamination, the minimum required POC is the extent of plume contamination on and off the property from an on-property release, as shown in Figures II-9A and II-9B. A remediator may choose to use a larger point of compliance by including all areas on the property which have been affected by an upgradient release. In this example, the remediator could choose to use the entire area shown as being affected by the upgradient release as the POC. In such a case, the remediator would receive liability protection for the entire area affected by the upgradient release.

The POC for the background standard in soil is throughout the area of the soil that has been contaminated (see 25 Pa. Code § 250.203(b)).

For surface water, point source discharges shall be measured at the point of discharge in accordance with limits in the National Pollutant Discharge Elimination System (NPDES) permit (see 25 Pa. Code § 250.203(c)). For spring or diffuse groundwater flow to surface waters, attainment of the background standard for groundwater will satisfy Act 2.

d) Establishing Background Concentration(s)

Background concentrations are determined using analysis of samples of regulated substances present at the property under investigation but not related to any release at the property. If all areas on the property are affected by a release at the property, then background samples will be taken in an area free of contamination from any release at the site, including representative off-property areas. Persons may not obtain Chapter 5 cleanup liability protection by using a contaminated area as a background reference area when they are responsible for the contamination.

Background soil sampling locations must be representative of background conditions for the site, including soil type; physical, chemical, or biological characteristics; and depth below ground surface. Randomization of sampling at background and onsite locations must be comparable (see 25 Pa. Code § 250.204(f)(7)).

Any wells that are used to establish groundwater concentration(s) must be hydrogeologically upgradient or otherwise justified from the groundwater onsite that is affected by any release at the property and that characterizes the flow onto the site. Upgradient wells may not be appropriate to detect movement of a dense non-aqueous phase liquid (DNAPL) since geologic structure rather than hydrogeologic gradient may influence DNAPL movement.

Background concentrations determination will be by a statistically valid method that is consistent with the methods used to demonstrate attainment. Statistical methods are included in 25 Pa. Code § 250.707 and in Section II.B.1(e)(vi) of this manual.

Figure II-7: Point of Compliance for the Background Standard Compliance with Background Standard from Upgradient Release with No On-Property Release

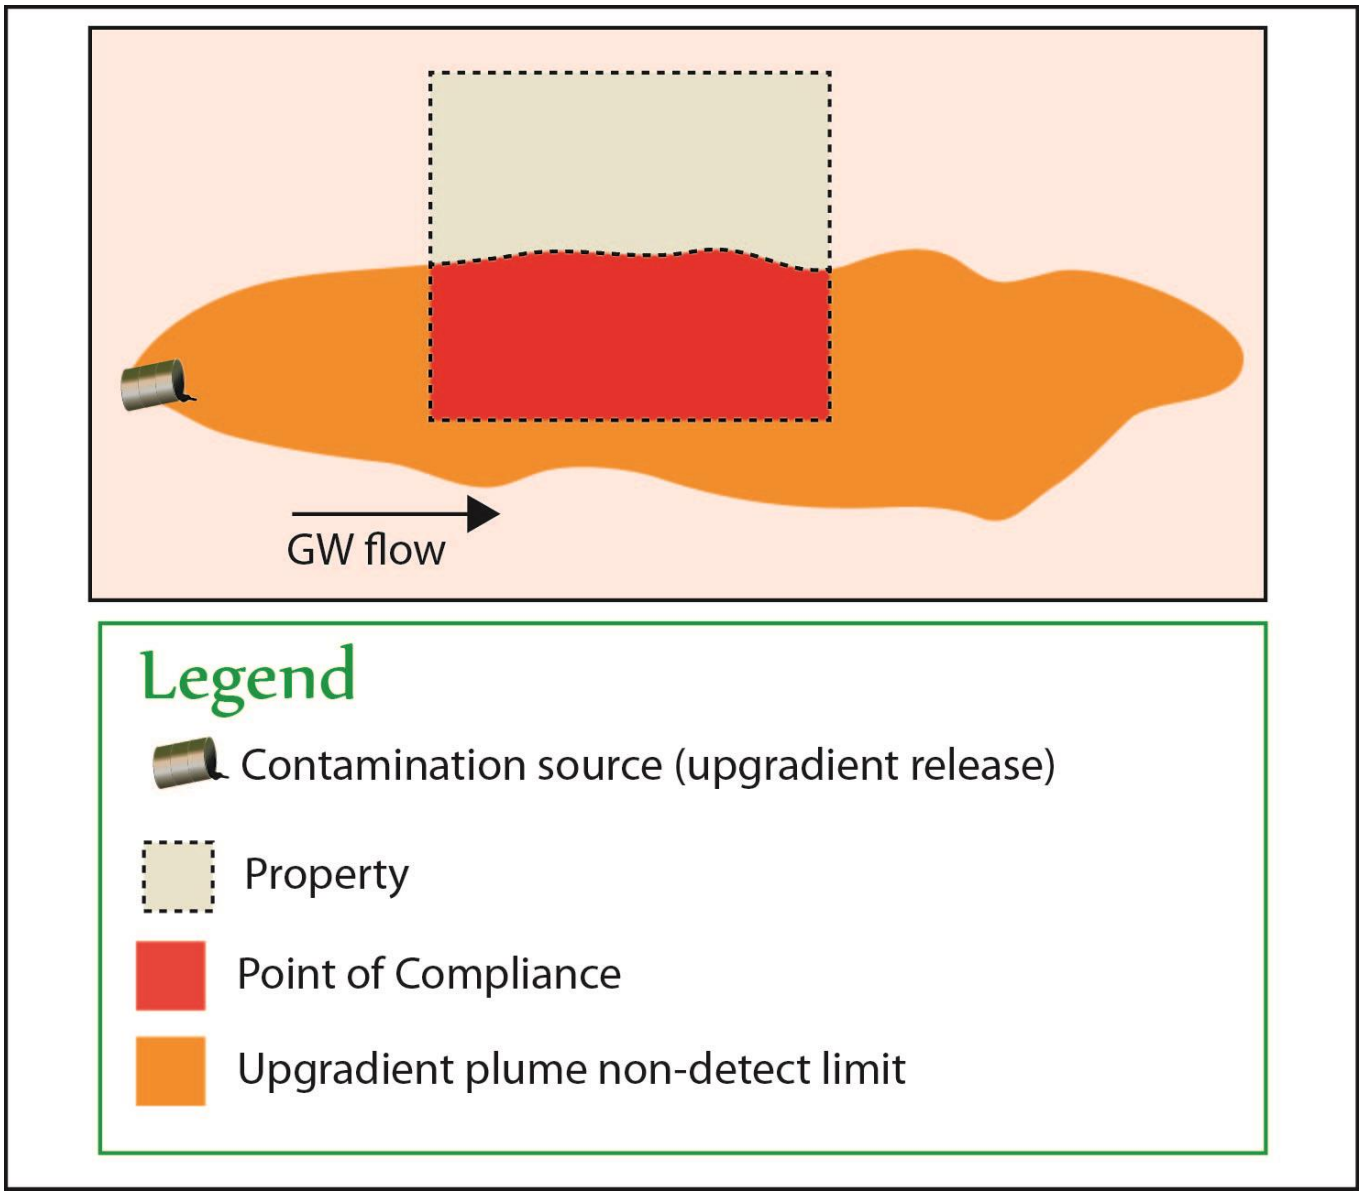

Figure II-8: Point of Compliance for the Background Standard Off-Property Migration with an Upgradient Groundwater Source Area Release

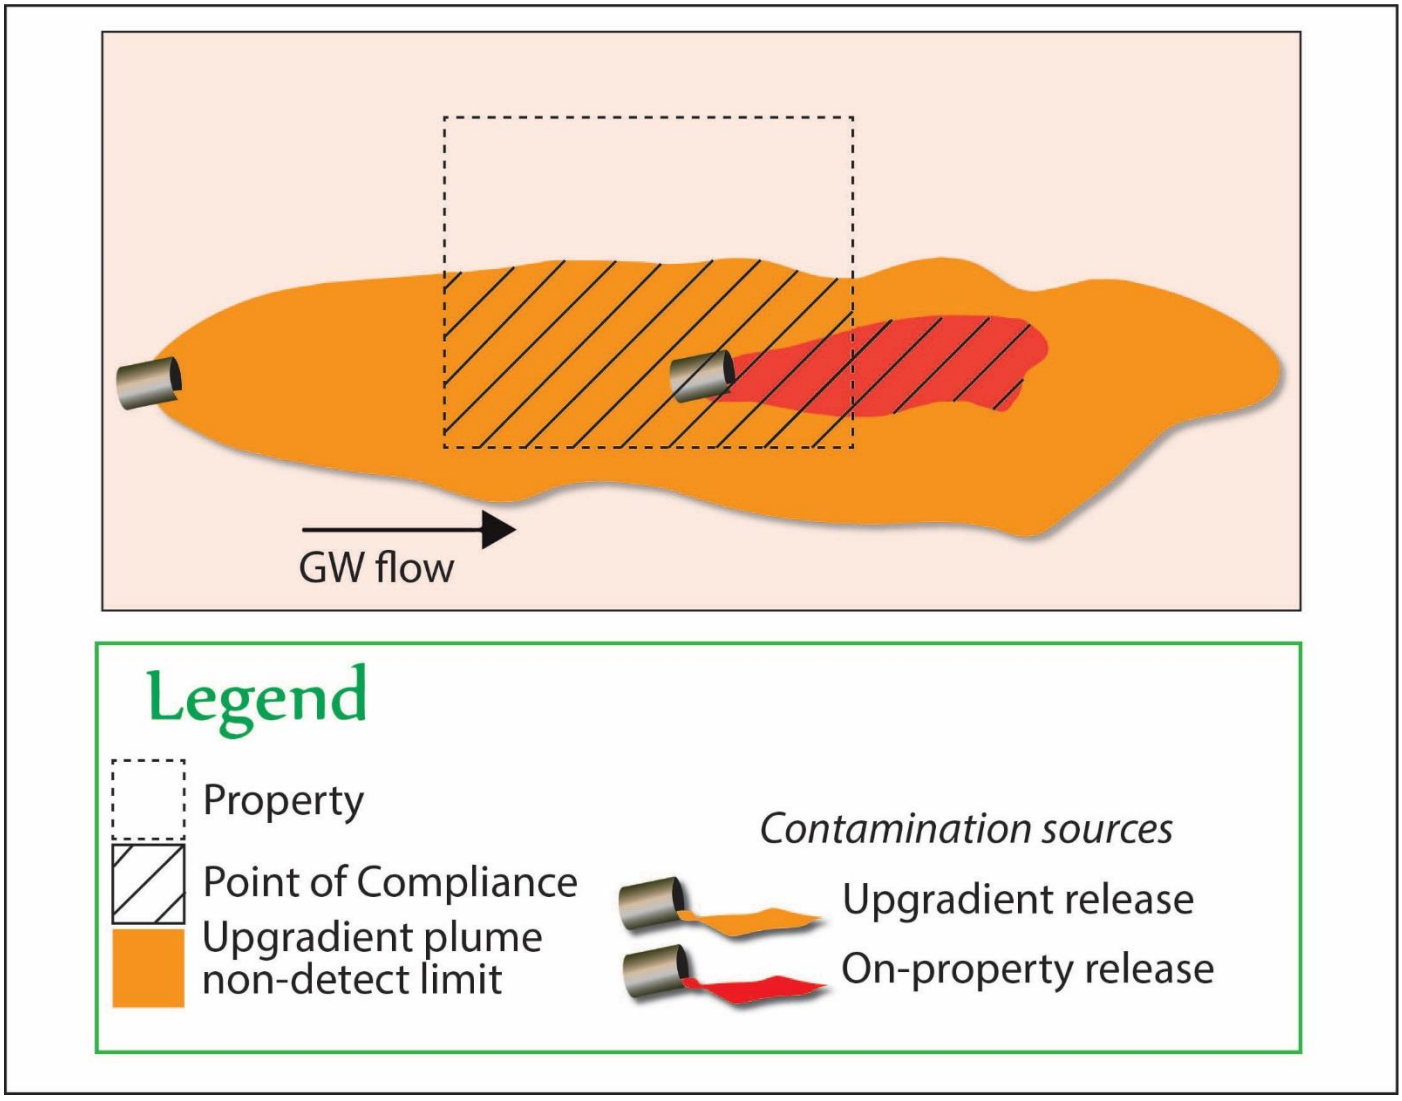

Figure II-9A and 9B: Areawide Contamination Scenarios

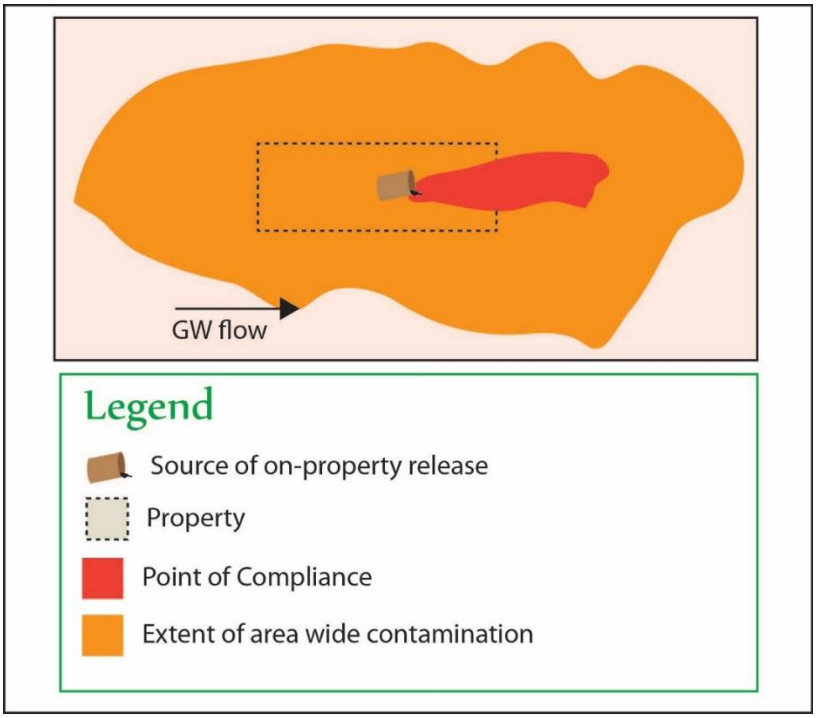
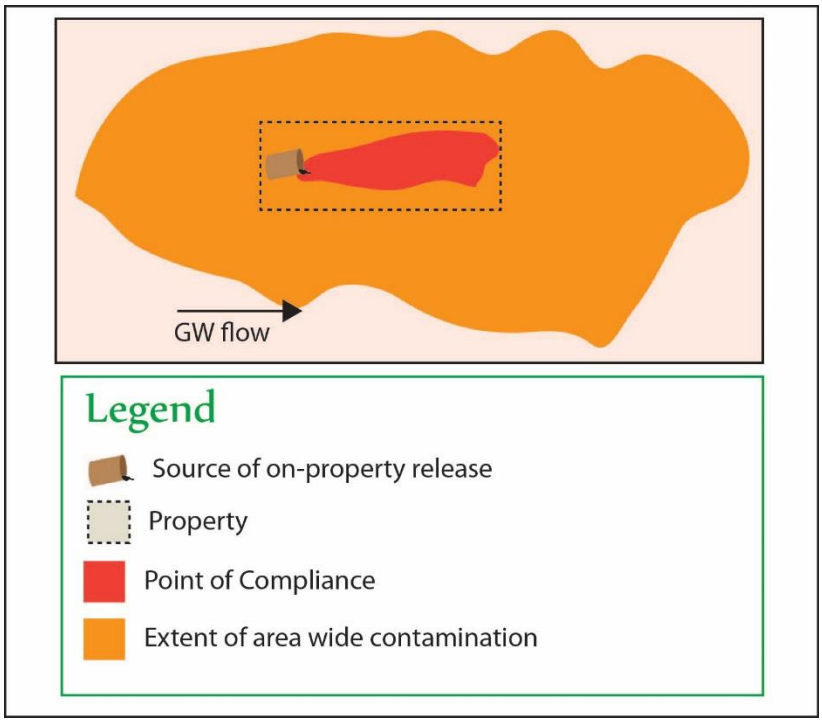




For non-naturally occurring regulated substances (primarily organic compounds) the affected area shall be shown to be related to sources other than the release of regulated substance on the site. This may include transport of regulated substances onto the property in the gaseous, liquid, or solid phases and associated mixing with or partitioning to onsite gaseous, liquid, or solid-phase media. For background conditions that are related to ongoing flux onto the site (e.g., regulated substances dissolved in groundwater flowing onto the site or soil vapor transport onto the site), the background concentrations shall be determined by monitoring the concentrations of regulated substances associated with this flux where it enters the property. For background conditions that are not related to a continuing source of chemical flux onto the property (e.g., historical accumulation of airborne contaminants including particulate and associated deposition in surficial soils), the determination of background concentrations shall include the identification of the source(s), if possible, and a demonstration that the areal distribution of the background conditions extends beyond the limits of the property.

These same determinations should be made for naturally occurring regulated substances. However, an additional determination should be made as to the naturally occurring concentrations of these regulated substances independent of impacts from the release(s) or other background sources. Therefore, for naturally occurring regulated substances, the background standard would include the naturally occurring concentration plus contributions from sources not on the property.

Use of breakdown products of a regulated substance from offsite which form on the site undergoing remediation can be included in the assessment of attainment of the background standard. The Department is willing to consider breakdown products of substances released upgradient of the property. The remediator should submit historical information and fate and transport analyses to demonstrate that the substances onsite are a result of chemical breakdown and not a result of a release on the property. Likewise, a conclusion that contamination entering a subject property which transforms or degrades to a compound similar to a spill which occurred on the subject property will be supported by the combined sample analysis and fate and transport analysis determination. The remediator must demonstrate that the concentrations are the result of transformation or direct migration of chemicals from the background area.

The establishment of the groundwater background concentrations for a site using sampling and analysis allows for two different background conditions, as described in 25 Pa. Code § 250.707(a):

- Background from a known upgradient release of regulated substance.

- Background from naturally occurring or areawide contamination (this can also apply to soils).

The Department provides different procedures to establish the background groundwater concentration depending on which background condition is present

upgradient and adjacent to the property. The method used when establishing background and determining attainment of the background standard for a site must be the same.

i) Background from a Known Upgradient Release of a Regulated Substance

(a) Groundwater

This groundwater distinction occurs when an adjacent or nearby property has had a release of the same regulated substance that flows onto the property under consideration for an Act 2 remediation. One option for determining background conditions is through the use of monitoring wells sampled during the site characterization to establish the well with the highest concentration of the groundwater migrating onto the site. Another option is to compare the statistical distribution of the background area with the impacted area onsite. Section 250.707(a)(2) in the regulations, Section II.B.1.e.vi of this manual, and the statistical requirements in Section III.B of this manual discuss the handling of the statistical requirements for groundwater attainment in the background standard.

A remediator who believes that a site meets the conditions for reducing the timeframe for implementing eight groundwater sampling events as found in 25 Pa. Code § 250.707(a)(2)(x), and already has eight or more samples collected in four quarters or less, may request that the Department accept fewer than eight quarters of sampling. The request may be submitted with supporting information to the Regional ECB Program Manager. If the Department is not satisfied that these conditions are met, the remediator shall continue to monitor for the remainder of the eight quarters.

The time frame for taking the background samples when remediation is not undertaken may start before the site characterization is completed. This will allow a remediator who has existing data to establish background without the need to monitor for an additional four or eight quarters if all the consecutive quarterly data total four or eight quarters, as applicable to that background condition.

If remediation action is undertaken, the attainment sampling is done after remediation is completed.

(b) Soil

Soils where a large area was affected by a release of regulated substances off-property do not typically move from one location to

another in comparison with the movement of groundwater. Natural movement of soil in Pennsylvania normally involves surface water transporting sediment, landslides, or airborne transport of soil or contaminants.

ii) Background from Naturally Occurring or Area-wide Contamination

Some areas of the Commonwealth have naturally occurring or widespread contamination. A remediator should obtain a written agreement from the Department if they plan to demonstrate that their site is in an area of naturally occurring or widespread contamination. This decision will be based on evidence presented to the Department in writing by the remediator seeking the determination. When the Department agrees, through written acknowledgment to the remediator that the property under investigation is within a location of areawide contamination, the following approach for establishing background is allowed.

(a) Groundwater

When the background groundwater condition is due to naturally occurring or areawide contamination, a minimum of 12 samples should be collected offsite and 12 samples collected onsite. The number of wells sampled onsite and offsite must be the same in each round of sampling. For example, if three wells are sampled offsite, three wells must be sampled onsite. In this example, each of the wells must be sampled a minimum of four times. The samples must be independent of one another. The onsite and offsite samples must be collected at the same time. The time frame for establishing this condition is not predetermined, as it is in the upgradient release. By increasing the number of wells onsite and offsite, the number of sampling events necessary to meet the minimum of 12 samples can be reduced (two wells will require six sampling events, six wells will require two sampling events). The offsite wells must be located upgradient of the site. The number of wells and the horizontal and vertical location of the wells onsite must be adequate to characterize any release of regulated substance at each site. All sampling data must be reported to the Department.

(b) Soil

When the background soil condition is due to naturally occurring or areawide contamination, the remediator shall compare the analytical results of background reference samples that are representative of naturally occurring or areawide contamination of substances on the site, with the analytical results of onsite concentrations. A minimum of 10 samples should be collected offsite or at the background referenced area, and 10 samples collected onsite. The comparison should be conducted using the

statistical methods summarized in 25 Pa. Code § 250.707(a)(1) and in Section III.B of this manual.

(c) Historic Fill

Some sites may be located in an area where there has been widespread use of fill (Figure II-10). This fill may contain regulated substances. If a spill or discharge of a regulated substance occurs on a site that received fill long ago (historic fill), the remediator can limit his remediation to the discharge that he or she has recently caused. In this case, the remediator would obtain relief from liability only for cleaning up what the remediator has recently spilled. This includes contamination resulting from the onsite release to the soil and groundwater. Remediators who wish to limit their cleanup to the levels that were already present in the fill should provide information to the Department indicating that the fill was historical (placed prior to 1980), not placed at their direction, and widespread or involved more than the subject property.

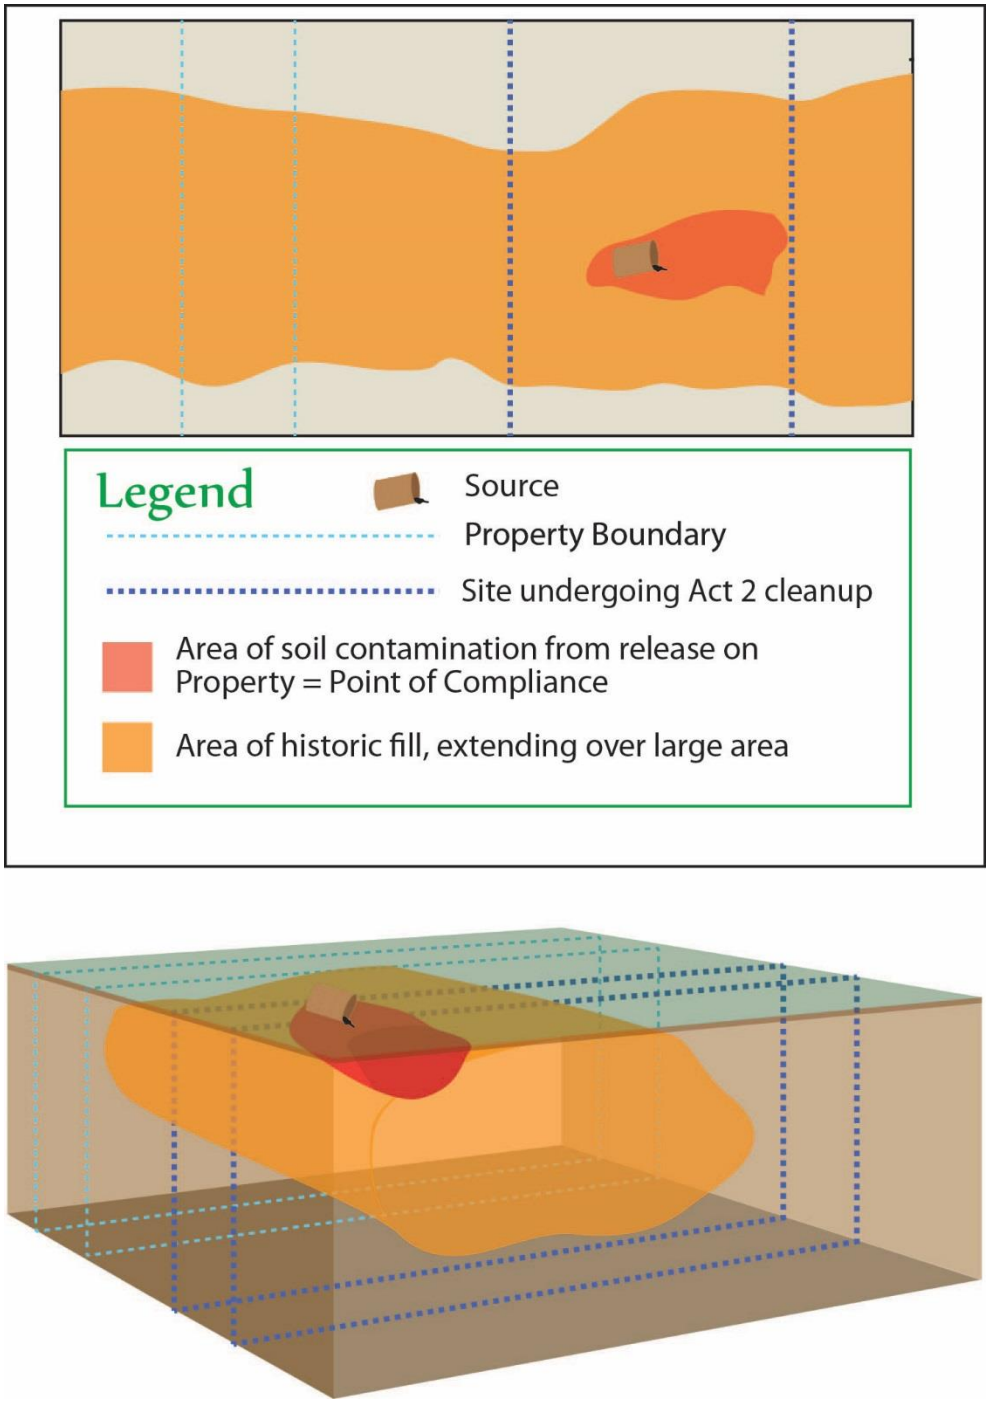
An example of contamination that may have occurred through airborne transport comes from the time when leaded gasoline was commonly used in automobiles. The surface and near-surface soils of properties along highways have been found to have elevated levels of lead. Samples taken from a number of properties near and along the highways would be required to compare the onsite and offsite conditions.

e) Final Report Requirements for the Background Standard

For a site remediated under the background standard, the remediator shall submit a final report to the Department which documents attainment of the selected standard. Section 250.204 of the regulations discusses final report requirements.

A complete final report is prepared in accordance with scientifically recognized principles, standards, and procedures. The report will present a thorough understanding of the site conditions. It will provide a detailed discussion on the AOC and a conceptual site model based on the results of the site characterization. Support for interpretations and conclusions will be based on data collected during all of the investigations at the site. The level of detail in the investigation and methods selected need to be sufficient to define the rate, extent, and movement of the contaminants to assure continued attainment of the remediation standard. In accordance with 25 Pa. Code § 250.204(a), all interpretations of geologic and hydrogeologic data shall be prepared by a professional geologist licensed in Pennsylvania.

Figure II-10: Background Standard Attainment with Areawide Fill



Two copies of the final report should be submitted for the Department's review. One should be a paper copy and the other should be submitted in another format (CD, flash drive, etc.). The final report must include the information in paragraphs (i)-(xi) of this section, and it should be organized according to the outline in Table II-1, below.

The following paragraphs describe the information to be included in the final report:

i) Summary

The Final Report Summary form should be filled in and submitted to the Department electronically. The summary submitted with the final report should be a copy of that completed form.

ii) Site Description

Provide a description of the site in sufficient detail to give the reviewer an overall understanding of the site and its location, and the types of operations that are currently and/or were formerly conducted on the site. As appropriate to the site, the description should include location, physical description of the property, ownership history, site use history, and regulatory action history (past cleanups).

iii) Site Characterization

The site characterization provides important information documenting the current conditions at the site and shall be based on 25 Pa. Code § 250.204. The two principal objectives of an investigation under the background standard are to determine what constitutes background for each of the regulated substances associated with the release, and to characterize the nature, extent, direction, volume and composition of regulated substances that have been released. Considerations for establishing the background concentrations are found in Section II.B.1.d. Section 250.204 of the regulations provides reporting requirements for the background standard.

For sites where there are multiple distinct areas of contamination, the site characterization process should be applied to each area individually.

Table II-1: Suggested Outline for a Final Report under the Background Standard

I. Final Report Summary

The final report summary should be a copy of the electronic form submitted to the Department.

II. Site Description

Provide a description of the site in sufficient detail to give an overall view of the site (Section II.B.1(e)(ii)).

III. Site Characterization

Document current conditions at the site (25 Pa. Code § 250.204 and Section II.B.1(e)(iii)).

IV. Background Standard

Describe how the background standard was established (Section II.B.1(e)(iv)).

V. Remediation

Describe the remedial methodologies used to attain the selected standard (Section II.B.1(e)(v)).

VI. Attainment

A. Soil background standard

B. Groundwater background standard

Both sections A and B should describe the statistical methods used to establish background and to demonstrate attainment of the standard (Section II.B.1(e)(vi)).

VII. Fate and Transport Analysis

Describe fate and transport analyses used and the results and conclusions (Section II.B.1(e)(vii)).

VIII. Postremediation Care Plan

This section is included only if necessary. It describes the engineering and institutional controls necessary to maintain the standard (Section II.B.1(e)(viii)).

IX. References

(Section II.B.1(e)(ix))

X. Attachments

(Section II.B.1(e)(x))

XI. Signatures

(Section II.B.1(e)(xi))

Along with a narrative, the results from the site characterization and all sampling and analysis work should be provided on map(s) illustrating, to the extent possible, the interrelationship of the following:

- All physical site characteristics.
- All groundwater, soil, sediment, and other sample locations, including sample depth and contaminant concentration.
- The surveyed locations for all assessment structures (monitoring wells, soil borings, test pits, etc.). All elevations should be reported in reference to mean sea level (msl), where practical.
- Appropriate number of stratigraphic cross sections that adequately depict site stratigraphy, well locations, well depths, groundwater flow directions, equipotential lines, flow lines, hydraulic conductivity intervals and values, sampling intervals and concentrations. All elevations should be reported in reference to msl, where practical.
- Variation in potentiometric surfaces(s), potentiometric surface map(s), hydraulic gradients, and groundwater flow directions.
- All identified sources of releases.
- The extent and concentrations of contaminant plumes in all media. The horizontal and vertical extent of contaminant plumes, including the relative density and thickness of any separate phase liquids (SPL) present.
- Top of bedrock contour (if encountered).

A conceptual site model should be developed and refined as information is gathered during the site characterization. The conceptual site model provides a description of the site and extent of contamination. Some of the information and data used to develop the site model would include:

- The type, estimated volume, composition, and nature of the released materials, chemicals or chemical compounds (include all calculations and assumptions).
- Source(s) and extent of release(s).
- Background concentrations for constituents of concern.
- The horizontal and vertical extent of contamination.

- Affected aquifer(s) or water bearing formation(s)/member(s), hydrostratigraphic units.

- All existing and potential migration pathways.

- The estimated volume of contaminated soil and water (include all calculations and any assumptions).

For soils, include information on samples and measurements used to characterize the horizontal and vertical extent of contamination, and the direction and rate of contaminant movement based on factors in the soil and the contaminant(s) which affect migration. Soil and boring descriptions should be included as an attachment.

For groundwater, include information on samples and measurements used to characterize the horizontal and vertical extent of contamination, and the direction and velocity of contaminant movement based on factors of the groundwater and the contaminant(s) which affect migration. Geologic boring descriptions and as-built drawings of wells should be included as an attachment. Text, tables, graphics, figures, maps, and cross sections, as appropriate, can be utilized to describe the nature, location, and composition of the regulated substances at the site. Providing the data in an appropriate format will expedite the review of the report.

iv) Background Standard

- How the background concentration was established.

- Type of background condition: upgradient release or area-wide contamination.

- Identify on a map the location of background soil samples and background groundwater wells.

- Document that POC attainment for groundwater is throughout the plume.

- Attainment for each medium is to be determined by the same method as the method used to establish background levels.

- Summary of sampling methodology and analytical results relating to determination of background.

v) Remediation

Provide a description of the remedial methodologies used to attain the selected standard. Examples of the types of information typically included in this section include:

- Identification of areas remediated based on results of site characterization.
- Descriptions of treatment, removal, or decontamination procedures performed in remediation. Description of removal, what was removed, and amount removed. Results of any treatability, bench scale, or pilot scale studies, or other data collected to support the remedial action(s).
- Description of the methodology and analytical results used to direct the remediation and determine the cessation of remediation. This description should document how the remediator determined that remediation was performed to address all areas that exceed the standard.
- Description of treatment technologies.
- Documentation of handling of remediation wastes in accordance with applicable regulations.
- Specific characteristics of the site that affected the implementation or effectiveness of the remedial action, including such characteristics as topography, geology, depth of bedrock, potentiometric surfaces, and the existence of utilities.
- All other site information relevant to the conceptual design, construction, or operation of the remedial action.

In addition to the above, this section should also include the calculation of the mass of contaminants addressed during the remediation of soil and/or groundwater, using the methodology in Section III.D.

vi) Attainment

Appropriate statistical methods, discussed in Section III.B, will confirm the attainment of cleanup under the background standard. Not all the statistical tests discussed in the manual are appropriate for the background standard attainment tests. Section 250.707(a) of the regulations describes statistical tests for the background standard. The following information shall be documented in a final report when a statistical method is applied, except for the highest measurement comparison test described in § 250.707(a)(1)(i) of the regulations:

- Description of the statistical method and the underlying assumptions of the method.

- A clear statement of the applicable decision rule in the form of a statistical hypothesis for each spatial unit and temporal boundary, including the applicable statistical parameter of interest and the specific cleanup standard.

- Documentation showing that the sample data set meets the underlying assumptions of the method and explaining why the method is appropriate to apply to the data.

- Specification of false positive and false negative rates.

- Documentation of input and output data for the statistical test, presented in table and figures, or both, as appropriate; and identification, by medium, contamination levels remaining onsite.

- An interpretation and conclusion of the statistical test.

In demonstrating attainment of the background standard, concentrations of regulated substances are not required to be less than the limit related to the PQL for that substance as provided for in § 250.701(c) of the regulations.

(a) Soil Background Standards

The determination of attainment of soil background standards will be based on a comparison of the distributions of the background concentrations of a regulated substance with the concentrations in an impacted area. Act 2 regulations allow a person to use highest measurement comparison, combination of Mann-Wilcoxon Rank Sum (WRS) test and Quantile test, or other appropriate methods to demonstrate attainment of background standards. No matter which method is used, Act 2 regulations require that the minimum number of soil samples to be collected is 10 from the background reference area and 10 from each cleanup unit. This requirement of 10 samples is to ensure that any selected statistical test has sufficient power to detect contamination.

(b) Groundwater Background Standards

There are two general categories of background conditions for groundwater. The first is naturally occurring background or area-wide contamination. The second is background associated with a release of regulated substances at a location upgradient from the site that may be subject to such patterns and trends.

For naturally occurring background or areawide contamination, it is recommended that a minimum of 12 samples be collected from

any combination of upgradient monitoring wells, provided that all data collected are used in determination of background concentrations. This same number of samples must then be collected from monitoring wells impacted by a release on the site during the same sampling event. In both cases, this sampling may be accelerated such that all samples are collected as quickly as possible so long as the frequency does not result in serial correlation in the data. The resulting values may be compared using either nonparametric or parametric methods to compare the two populations, such as using the combination of the WRS test and the Quantile test. When comparing with the background results, the sampling results in the plume onsite should not exceed the sum of the arithmetic average and three times standard deviation calculated for the background reference area 25 Pa. Code § 250.707(a)(3)(vii).

For background associated with a release of regulated substances at a location upgradient from a property, the background groundwater concentrations will be determined at the hydrogeologically upgradient property line of the property, or a point hydrogeologically upgradient from the upgradient property line that is unaffected by the release.

Section 250.707(a)(2) of the regulations allows the use of the nonparametric tolerance limit procedure for background associated with an upgradient release of regulated substances. The nonparametric tolerance limit procedure requires at least eight samples from each well over eight quarters in order to have sufficient power to detect contamination. Once the nonparametric upper tolerance limit is established for upgradient data, data from downgradient compliance wells can be compared to the limit. A resampling strategy can be used when an analyte exceeds the nonparametric upper tolerance limit. The well is retested for the analyte of concern and the value is compared to the nonparametric upper prediction limit. These two-phase testing strategies can be very effective tools for controlling the facility-wide false positive rate while maintaining a high power of detecting contamination. See Chapter 19 of the EPA Unified Guidance (EPA 530-R-09-007, U.S. EPA, March 2009), which describes the procedures to use.

vii) Fate and Transport Analysis

The Fate and Transport Section (Section III.A) of this manual provides a discussion on fate and transport analysis. The amount of detail in the fate and transport analysis will vary from a simple narrative description to a very extensive detailed model with quantitative modeling as appropriate to the circumstances of the site. Whenever a model is used, the Department must be provided with the assumptions, data, and information on the model necessary for Department staff to evaluate and run the model. Any

parameters used in the analysis or models should use data obtained from the site during the site characterization.

The following are examples of situations where a fate and transport model/analysis is used to justify a special condition when attaining the background standard:

- When shortening the number of groundwater samples for establishing an upgradient release in the background determination (25 Pa. Code § 250.707(a)(2)(x)), it is required that fate and transport be fully evaluated.

- When contamination remains in the unsaturated soil, fate and transport must demonstrate that the contamination in the soils will not impact the groundwater and raise the level of regulated substances above the groundwater standard. This would apply to both the soils and groundwater attaining the background standard or when using a combination of standards; for example, background standard in the groundwater and SHS in the soils.

- When the contamination on the site is the result of chemical transformations (e.g., parent to daughter), fate and transport must demonstrate that the concentrations of regulated substances onsite were the result of offsite releases.

While the previous examples will require detailed evaluation, when the source and any regulated substance that could have migrated from the source are removed before contamination reached the groundwater, the fate and transport analysis could be very short and non-quantitative.

When the background standard is attained in all media, the fate and transport analysis will confirm that no cross-media contamination will cause contamination in one medium to raise the contamination in another medium above the standard.

If the standard will be exceeded in the future, a postremediation care plan is required.

viii) Postremediation Care Plan (if applicable)

If engineering or institutional controls are needed to maintain the standard, a postremediation care plan must be documented in the final report in accordance with 25 Pa. Code § 250.204(g). The plan should include reporting of any instances of non-attainment; reporting of any measure to correct non-attainment conditions; periodic reporting of monitoring; sampling and analysis as required by the Department; maintenance of records at the property where the remediation is being conducted for monitoring, sampling and analysis; and a schedule for operation and maintenance of the controls and submission of any proposed changes. The

Department may ask for documentation of financial ability to implement the remedy and to maintain the postremediation care controls. When the standard can be maintained without the controls operating and documentation of such is provided, the Department will approve termination of the postremediation care program.

ix) References

Any references mentioned in the final report.

x) Attachments

Attachments may include but are not limited to:

- Tables – monitoring well construction summary, groundwater gauging data (including elevation and non-aqueous phase liquid (NAPL) thicknesses), analytical data, historical data.
- Figures – including groundwater elevation maps, extent of NAPL, concentration data for soil/groundwater/surface water, cross-sections.
- Monitoring well construction diagrams, boring logs, stratigraphic logs (including soil/rock characteristics).
- Sampling and analysis plan(s).
- Quality Assurance (QA) and Quality Control (QC)Plan.
- Well search documentation (from PaGWIS).
- Field data sheets, such as low flow purging monitoring.
- Statistical worksheets, software outputs, graphs, etc.
- Disposal documentation of soil/groundwater.
- Remediation system operation, maintenance, monitoring data; mass removal estimates.
- Before and after remediation photographs.
- Copy of municipal notification, reasonable proof of newspaper notice publication, Department acknowledgement of natural or area-wide contamination.

xi) Signatures

If any portions of the submitted report were prepared or reviewed by or under the responsible charge of a registered professional geologist or engineer, the professional geologist or engineer in charge must sign and seal the report.

2. Statewide Health Standard

a) Introduction

The SHS is established by Sections 301 and 303 of Act 2 (35 P.S. §§ 6026.301 and 6026.303) and includes MSCs that must be attained to achieve the liability protection provided for in the Act. The MSCs are calculated in accordance with the methodologies in § 250.304 through 250.310 of the regulations.

The numerical MSCs are contained in Appendix A to Chapter 250, Tables 1 through 6. Cleanup liability protection provided under Act 2 is contingent upon the attainment of the appropriate MSCs determined using the procedure described in Section II.B.2(c) below.

This guidance presents the procedures to be used in assessing site contamination and demonstrating attainment of the SHS. Use of this guidance and data submission formats should simplify reporting on the site and reduce delays in obtaining final report approval by the Department. This guidance is designed to aid in understanding and meeting the requirements of the SHS under Act 2 and the regulations in Chapter 250. ECB staff in the Regional Office are a valuable resource and will assist as requested in answering questions on the SHS.

Failure to demonstrate attainment of the SHS may result in the Department requiring additional remediation measures to be taken to meet the SHS; or the remediator may elect to attain one of the other standards.

b) Process Checklist for Remediations Under the Statewide Health Standard

☐ Review the historical information and present use of regulated substances at the property.

☐ Begin site investigation/characterization and gather information about the area on and around the property.

☐ Optional: Begin using the completeness list (see LRP webpage) to help verify that all requirements have been met.

☐ Optional: Determine if the property/site is affected by regulated substances not from the property to determine if the background standard may be appropriate. Contact DEP Regional Office for information.

☐ Submit an NIR for the SHS. Also, provide notice to the municipality, publish a notice in a local newspaper, and obtain reasonable proof of submittal for inclusion with the final report. Procedures for submittal of notifications are contained in Section II.A.3 of this manual.

☐ Continue with the site characterization and required activities, including vapor intrusion evaluation (see Section IV of this manual), needed to complete the final report.

☐ Remediate the site to the SHS.

☐ Demonstrate attainment of the SHS. Methods for demonstrating attainment are described in 25 Pa. Code § 250.707(b) and in Section III.B of this manual.

☐ Calculate the mass of contaminants remediated using the procedure in Section III.D of this manual.

☐ Complete the Final Report Summary electronically in accordance with the instructions on the LRP webpage.

☐ Prepare and submit final report, along with the optional completeness list (if used), to the Department. Reporting requirements are established by 25 Pa. Code § 250.312 and are described in Section II.B.2(f) of this manual.

☐ A postremediation care program must be implemented and documented in the final report including the information required by § 250.204(g) of the regulations if: (1) engineering controls are needed to attain or maintain the SHS; (2 institutional controls are needed to maintain the standard; (3) the fate and transport analysis indicates that the remediation standard, including the solubility limitation, may be exceeded at the POC in the future; (4) the remediation relies on natural attenuation; (5) a postremedy use is relied upon but is not implemented to eliminate complete exposure pathways to ecological receptors; or, (6) mitigative measures are used.

☐ Submit an environmental covenant, if applicable, to the Department.

☐ Receive approval of the final report from the Department, if the final report documents that the person has demonstrated compliance with the substantive and procedural requirements of the SHS (which automatically confers the Act 2 liability protection as set forth in Chapter 5 of Act 2).

☐ Except for the special case of a nonuse aquifer standard (See Section II.B.4(c), when the SHS can be maintained without engineering controls operating, document this to the Department and receive approval to terminate the postremediation care program.

c) Selection of MSCs

The appropriate MSC for each regulated substance present at a site is determined for each environmental medium, particularly groundwater and soil. The decision tree in Figure II-11 illustrates the thought process that goes into the selection of the appropriate MSCs for groundwater and soil. If values for the compounds on a given site cannot be found in Tables 1 through 4, please check Table 6: Threshold of Regulation Compounds.

The values shown in the MSC tables are generally rounded to two significant figures. Due to rounding the numeric values for placement in the tables, the remediator is also permitted to round the concentrations reported by the laboratory to two significant figures for comparison to the MSC values.

For example: The chosen MSC value for a certain compound is 2.6 µg/L. If the laboratory reports a result of 2.629 µg/L, the remediator is permitted to round the laboratory's reported value to 2.6 µg/L and thus is able to attain the standard. However, if the laboratory's reported concentration is 2.678 µg/L, rounding to two significant figures results in a concentration of 2.7 µg/L and thus exceeds the MSC and is not able to attain the standard.

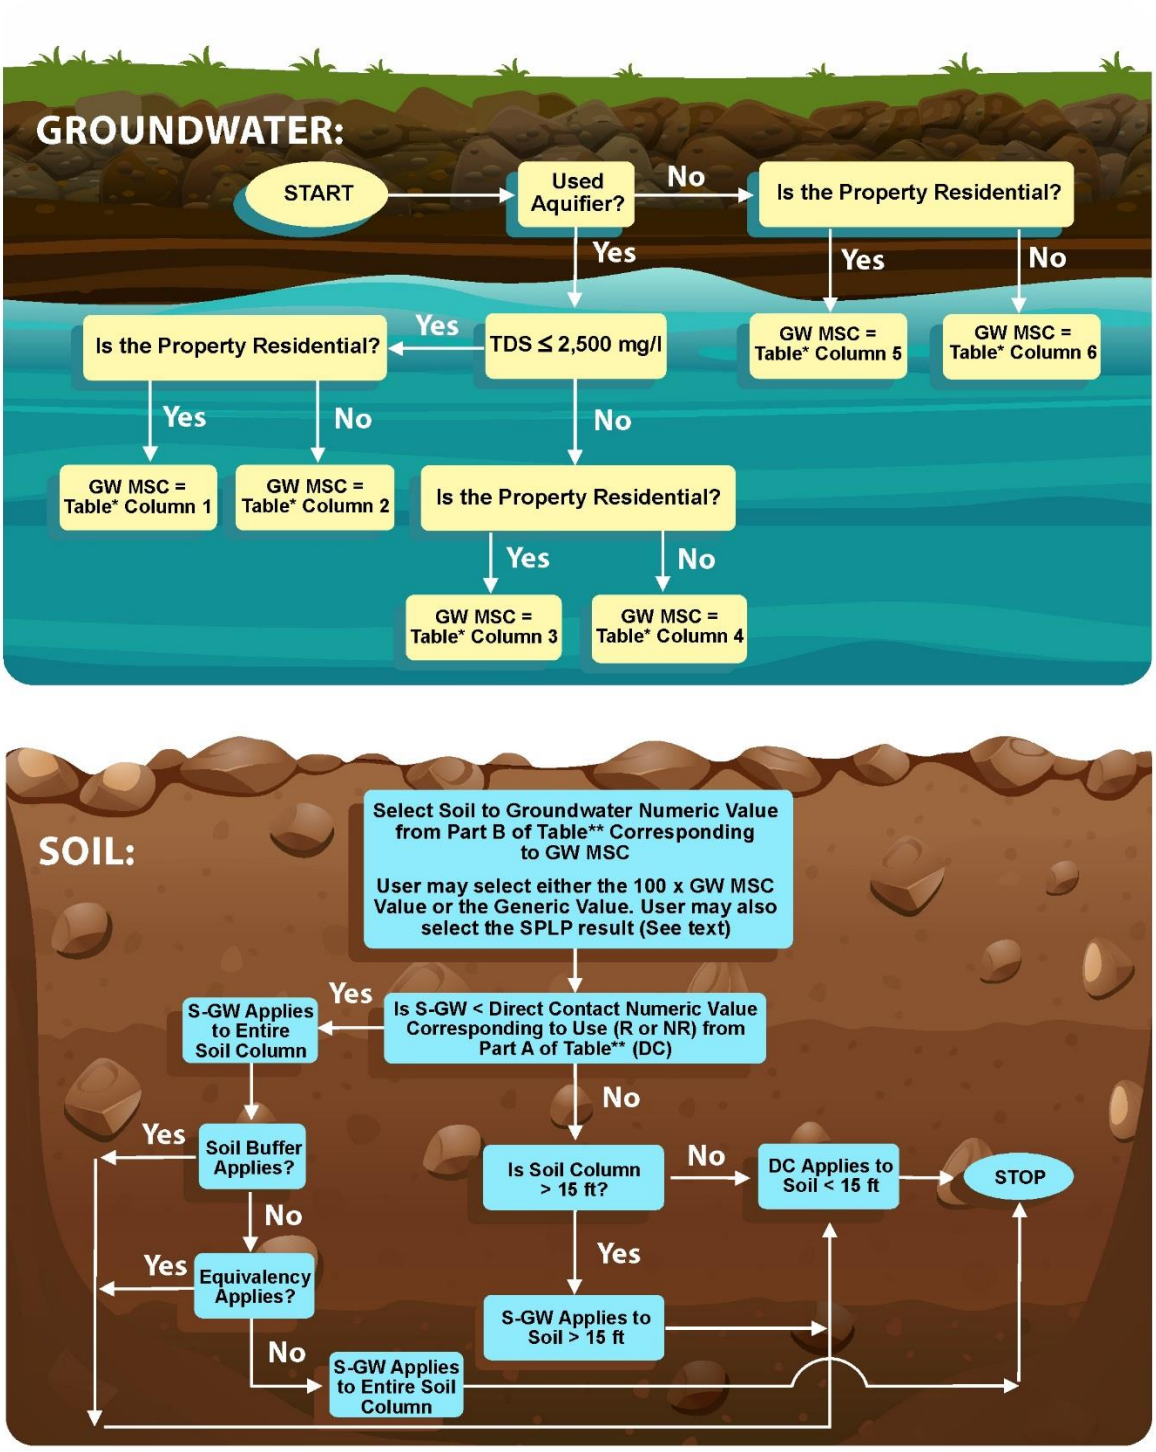
i) Determining Groundwater MSCs

MSCs for regulated substances in groundwater are found in Appendix A to Chapter 250, Table 1 for organic substances, and Table 2 for inorganic substances. To use the tables, the remediator needs to know the use status of the aquifer under the site, the naturally occurring level of Total Dissolved Solids (TDS) in the aquifer, and the land use of the site.

ii) Determining Soil MSCs

In determining the applicable soil standard, the remediator must compare the appropriate soil-to-groundwater numeric value to the direct contact numeric value for the corresponding depth interval within 15 feet from the ground surface. The lower of these two values is the applicable MSC for soil. If either the soil buffer distance (described in 25 Pa. Code § 250.308(b) and (c)) or the equivalency demonstration (described in 25 Pa. Code § 250.308(d)) is met, the soil-to-groundwater numeric value will be deemed to be satisfied, and the soil MSC will be the direct contact numeric value. The soil-to-groundwater numeric value is the MSC for soil at depths below 15 feet, unless either the soil buffer distance or the equivalency demonstration is met. These values are determined in the following manner:

Figure II-11: Decision Tree for Selecting Statewide Health Standard MSCs for Groundwater and Soil



* For Organic Regulated Substances, use Table 1; Use Table 2 for Inorganic Regulated Substances
** For Organic Regulated Substances, use Table 3; Use Table 4 for Inorganic Regulated Substances

Note: Figure must be used in conjunction with the text. Reference Section II.B.2.c)

(a) Choosing the Soil-To-Groundwater Numeric Value

The remediator should begin by determining the appropriate soil-to-groundwater numeric value from Part B of Table 3 for organics or Table 4 for inorganics. The numbers in the table include both the value which is 100 times the appropriate groundwater MSC and the number resulting from application of the soil-to-groundwater equation in the regulations (the "generic value"). The remediator must determine the use status of the aquifer underlying the site, its naturally occurring TDS level, and the land use characteristics of the site. The numeric value may then be selected from the appropriate column on the table and compared to the value for the Synthetic Precipitation Leaching Procedure (SPLP), if appropriate. Since the remediator has the choice of which soil-to-groundwater numeric value to use, the remediator may choose the highest of these three values (i.e., 100x GW MSC, the generic value, or the SPLP result) as the soil-to-groundwater numeric value. The remediator must keep in mind that for periodically saturated soils, the generic value to use in this selection process is one-tenth the value listed in the table (see § 250.308(a)(2)(ii) and (a)(4)(ii) of the regulations). The intent of the one-tenth of the generic numeric value provision in the soil-to-groundwater numeric value calculation is to account for the dilution in contaminant concentrations that occurs in soils that are periodically saturated which does not occur in unsaturated soil. For permanently saturated soils, contamination becomes a groundwater contamination issue as the soil is in constant contact with the groundwater rather than being only periodically saturated.

The value for the SPLP is the concentration of a regulated substance in soil at the site that does not produce a leachate in which the concentration of the regulated substance exceeds the groundwater MSC. Values for the SPLP could not be published in the tables of MSCs in the regulations because this test must be conducted on the actual site soil. The following procedure should be used to determine the alternative soil-to-groundwater value based upon the SPLP:

- During characterization, the remediator should obtain a minimum of ten samples from within the impacted soil area. The four samples with the highest total concentration of the regulated substance should be submitted for SPLP analysis. Samples obtained will be representative of the soil type and horizon impacted by the release of the regulated substance.

- Determine the lowest total concentration (TC) that generates a failing (leachate concentration greater than the

groundwater MSC) SPLP result. The alternative soil-to-groundwater standard will be the next lowest TC.

- If all samples have a passing (leachate concentration less than the groundwater MSC) SPLP result, the alternative soil-to-groundwater standard will be the TC corresponding to the highest SPLP result. The remediator has the option of obtaining additional samples.

- If all samples have a nondetect SPLP result, the alternative soil-to-groundwater standard will be the TC corresponding to the highest concentration of each contaminant. The remediator has the option of obtaining additional samples.

- If none of the samples generates a passing SPLP, the remediator can obtain additional samples and perform concurrent TC/SPLP analyses to satisfy the above requirements for establishing an alternative soil-to-groundwater standard.

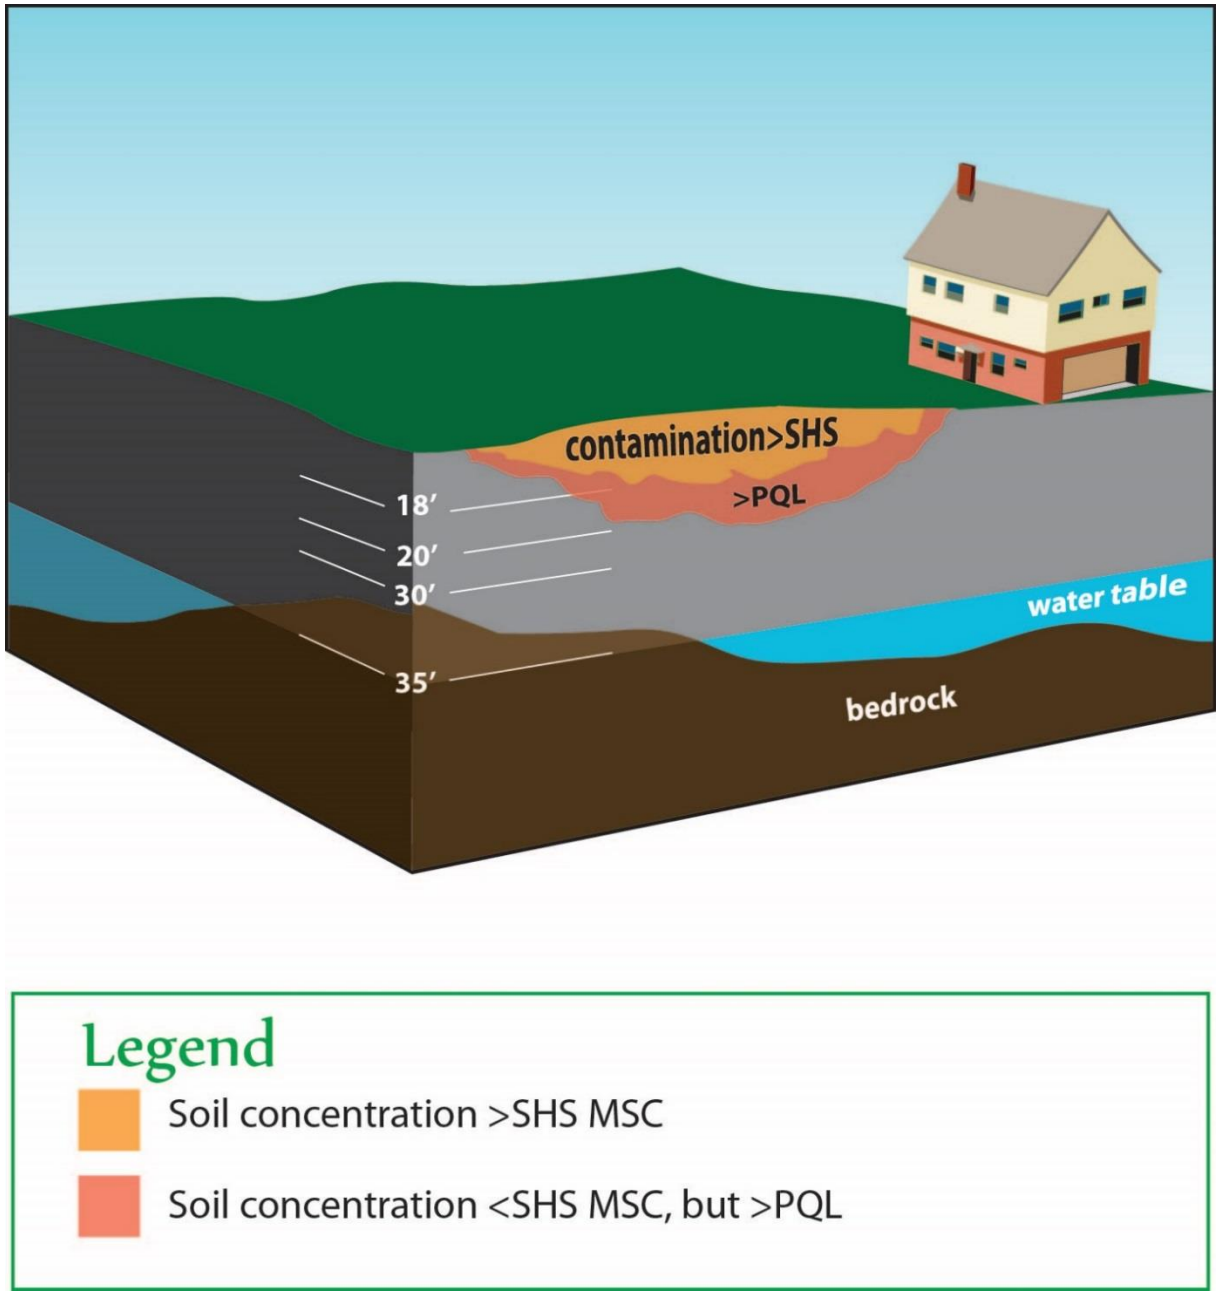
(b) Considering Direct Contact Value in Relation to the Soil-to-Groundwater Value and Soil Depth

The number selected according to the process outlined in Section II.B.3.b.i of this TGM for the soil-to-groundwater pathway numeric value must then be compared to the appropriate residential or nonresidential, surface or subsurface, direct contact numeric value from Part A of Table 3 or Table 4. The lower of the two numbers is the appropriate MSC for the regulated substance. If the soil buffer distance requirements are met or the equivalency demonstration has been made, then the soil-to-groundwater numeric value is deemed to be satisfied and the MSC is the appropriate direct contact numeric value for the regulated substance. The soil buffer approach incorporates fate and transport considerations; therefore, meeting the soil buffer requirements will not require any additional fate and transport analysis.

(c) Selecting Applicable MSCs – Example

The process for selecting the appropriate MSCs for a site is illustrated in Figure II-12. This figure represents the cross section of a nonresidential site with soil contaminated with a petroleum product. The aquifer does not qualify as a nonuse aquifer. The remediator is interested in determining and applying the soil MSCs under the SHS. This example shows the process applied to one of the regulated substances: cumene.

Figure II-12: Application of the MSC Selection Process



Details of the site determined during the site characterization are as follows (see also Figure II-12).

- Soil characterized as contaminated with regulated substances from the petroleum product, including cumene (concentration values > PQL, see Section III.G), is shown and extends to a depth of 20 feet. For this example, the remediator characterized the soil to the level of the PQL, but could have selected any concentration level between the SHS and the PQL, with the appropriate justification.

- Soil contaminated at levels greater than the applicable SHS is shown as a subset of the contaminated area and extends to a depth of 18 feet.

- Samples collected and analyzed according to the methodology in Section II.B.2(c)(ii)(a) established an alternative soil-to-groundwater value of 20 mg/kg.

- SPLP testing of site soil was established at 400 mg/kg.

- Shale bedrock is present at varying depths between 30 and 35 feet.

- The groundwater level is approximately 35 feet, but fluctuates (annual high and low) between 28 to 40 feet and the natural total dissolved solids level in the groundwater is 80 mg/L.

- The vertical distance from the bottom of the contaminated area to groundwater is h = 15 feet.

Scenario #1 - the above conditions apply, and in addition, the results of sample analysis of the groundwater show no values greater than 3,500 μg/L.

Scenario #2 - the above conditions apply, and in addition, free floating product (approximately 1 inch) is found on top of the groundwater level, and the concentration of cumene below the groundwater level is 5,000 μg/L.

The remediator takes the following steps to determine appropriate MSCs for cumene at this site.

Groundwater MSC:

1) For Scenario #1 AND Scenario #2: As a first step, turn to LRP regulations, Chapter 250, Appendix A, Table 1 - Medium-Specific Concentrations (MSCs) for Organic Substances in groundwater. The remediator looks for the row for cumene, under the headings "Used Aquifers," "TDS≤2500 mg/L," "NR" (for Nonresidential). The groundwater MSC is 3,500 μg/L.

Under Scenario #1, the remediator concludes that there is no aquifer area which exceeds the groundwater MSC (3,500 μg/L) and, therefore, no attainment demonstration is needed. Under Scenario #2, the remediator concludes that the aquifer area exceeds the groundwater MSC (3,500 μg/L) and, therefore, attainment demonstration is needed.

Soil MSC:

2) The remediator turns to Chapter 250, Appendix A, Table 3 – Medium-Specific Concentrations (MSCs) for Organic Substances in Soil, Part B, Soil to Groundwater Numeric Values. The remediator looks for the row for cumene, under the Headings "Used Aquifers," "TDS ≤ 2500 mg/L," "Nonresidential." The two values listed are:

- 100x GW MSC – 350 mg/kg
- Generic Value - 2,500 mg/kg

The remediator then looks over to the last column on the right for the soil buffer distance – 15 feet.

3) The remediator assesses the use of numeric soil-to-groundwater values. Three options exist under the regulations (§ 250.308).

- 100x GW MSC – 350 mg/kg
- Generic Value – 2,500 mg/kg
- SPLP value – 400 mg/kg (from analysis of site soil—see site characterization.

Among the three acceptable values, the generic value of 2,500 mg/kg is the highest. The remediator considers using this option, but first wants to see if the site could qualify for the remaining two options for satisfying the soil-to-groundwater numeric value, the soil buffer and groundwater equivalency options.

4) In examining the soil buffer option, the remediator checks to see if the site meets the three regulatory conditions under 25 Pa. Code § 250.308(b), which states:

(b) The soil-to-groundwater pathway soil buffer is the entire area between the bottom of the area of contamination and the groundwater or bedrock and shall meet the following criteria:

(1) The soil depths established in Appendix A, Tables 3B and 4B for each regulated substance.

(2) The concentration of the regulated substance cannot exceed the limit related to the PQL or background throughout the soil buffer.

(3) No karst carbonate formation underlies or is within 100 feet of the perimeter of the contaminated soil area. Karst carbonate formations are limestone or carbonate formations where the formations are greater than 5 feet thick and present at the topmost geologic unit. Areas mapped by the Pennsylvania Geologic Survey as underlain by carbonate formations are considered karst areas unless geologic studies demonstrate the absence of the formations underlying or within 100 feet of the perimeter of the contaminated soil area.

Scenario #1 - The remediator concludes that the site meets the conditions for use of the soil buffer alternative to satisfy the soil-to-groundwater numeric value and, therefore, only the direct contact numeric value applies and becomes the soil MSC for cumene.

Alternatively, the remediator could have considered use of the groundwater equivalency option [§ 250.308(d)], but this includes the condition that he/she monitor the groundwater for 8 quarters prior to submitting the final report. The remediator instead chooses the soil buffer option above.

Scenario #2 - The remediator concludes the site DOES NOT meet the conditions for use of the soil buffer alternative because h=0 since soil contamination extends to the water level and, therefore, there is no depth of clean soil between the bottom of contamination and the groundwater level.

The remediator then checks to see if the site meets the requirements for use of the groundwater equivalency option. (25 Pa. Code § 250.308(d) and Section II.B.6(d) of the Technical Manual). The site does NOT qualify because groundwater is contaminated above SHS and background.

Therefore, the remediator should consider BOTH the soil-to-groundwater numeric value and the direct contact (DC) value.

Chapter 250, Appendix A, Table 3A—Medium-Specific Concentrations (MSCs) for Organic Regulated Substances in Soil, Direct Contact Numeric Values states that the nonresidential numeric value for cumene is:

10,000 mg/kg applied to the 0'-2' zone in soil

10,000 mg/kg applied to the 2'-15' zone in soil.

The remediator chooses the soil-to-groundwater numeric value based on the generic value of 2,500 mg/kg, which applies to the zone(s) of the soil contaminated above this value:

Zone 1—0-18' (see Figure II-12)

Zone 2 – the "smear zone" in the soil column created by groundwater level movement – 28'--40.' Note that this zone also is considered saturated soil under Chapter 250.

Next, the remediator checks to see where each numeric value is applied:

	DC value	Soil-to-GW value	Resulting Soil MSC
Zone 0'-2'	10,000 mg/kg	2,500 mg/kg	2,500 mg/kg
Zone 2'-15'	10,000 mg/kg	2,500 mg/kg	2,500 mg/kg
Zone 15'-18'	NA	2,500 mg/kg	2,500 mg/kg

Zone 28’ to 40’	NA	400 mg/kg	400 mg/kg

Zone 28’ to 40’ is periodically saturated soil. The selection of the applicable soil MSC for this zone must consider the requirement that the published generic value be divided by 10. Therefore, the remediator may choose from the following values:

100x GW MSC	350 mg/kg
Generic Value	250 mg/kg (0.1 x published value)
SPLP Value	400 mg/kg

Therefore, the remediator chooses the SPLP result as the applicable soil MSC.

For both scenarios, analysis of any attainment samples (determined under Section II.B.2(f)(vii) of this manual) would be compared to the appropriate numeric value for the zone in which the sample was taken, and the attainment test (e.g., 75%/10x) would be applied to the sample set as a whole (e.g., the percentage of samples which exceeded the appropriate numeric value must be ≤ 25% and no sample may exceed the appropriate numeric value by more than 10 times [10x]).

d) Nonuse Aquifer Determinations

i) General

Section 250.303 of the regulations provides for options for requesting a nonuse aquifer determination. Anytime a person is proposing an area for nonuse aquifer determination, they must meet the notification requirements of 25 Pa. Code § 250.5, which are described in Section II.A.3, relating to public notice.

- A remediator may request from the Department approval to use alternative MSCs in groundwater at the POC when the aquifer under a site is not used or planned to be used for drinking water or agricultural purposes. This determination is to be requested by the remediator, and the Department’s concurrence must be obtained in writing before the remediation may begin. The notice requirements under the nonuse aquifer request are made separate from those under the NIR. Note that an NIR must be submitted with, or prior to, the nonuse aquifer determination request. Although not required, the Department suggests that this request be submitted in conjunction with an NIR.

A remediator may rely on a "nonuse aquifer certification area" (see below) as documentation that they have satisfied 25 Pa. Code § 250.303(c)(1), (2) and (3) FOR THE SPECIFIC AREA defined as a "nonuse aquifer certification area." If the area they are required to document extends beyond the nonuse aquifer certification area, the remediator still has the obligation to document those requirements in the area NOT covered by the nonuse aquifer certification area.

Another option a remediator may have is using the presence of a municipal ordinance meeting the performance requirements of Section III.E (relating to institutional controls and other postremedial measures) as documentation that the use restriction meets the requirements of 25 Pa. Code § 250.303(c)(1), (2) and (3) IN THE AREA SUBJECT TO THE ORDINANCE.

- Municipal authorities and political subdivisions may request determination that a specific geographic area meets the conditions of 25 Pa. Code § 250.303(c)(1), (2) and (3). The area in question is then referred to as a nonuse aquifer certification area.

ii) Request Initiated by a Remediator as Part of an NIR

This option would be used by a remediator who desires to use the alternative nonuse aquifer MSCs at a specific property. As detailed in 25 Pa. Code § 250.303(b) of the regulations, the area in which the determination is to be made includes the property itself, all areas within a radius of 1,000 ft. downgradient of the property boundary, and all areas where the contamination has migrated, or may reasonably be expected to migrate, at concentrations exceeding the MSC for groundwater used or currently planned to be used. In making the request, the remediator should provide the fate and transport analysis used to determine the area to which the contamination has migrated and is likely to migrate. The Department will accept or reject the remediator's request based primarily upon the adequacy of this analysis. The area determined is the area of geographic interest to which the conditions of 25 Pa. Code § 250.303(c) apply. A form, Request for Nonuse Aquifer Determination, is available on the Department's website to be used by a remediator to expedite the Department's review of a nonuse aquifer demonstration. Use of this form is optional.

iii) Nonuse Aquifer Conditions to be Met in the Area of Geographic Interest

The requirements for demonstrating that an aquifer is not used are contained in 25 Pa. Code § 250.303(c) of the regulations. The remediator may make this demonstration by conducting door-to-door surveys of all downgradient properties or by using other appropriate survey methods,

and by contacting all community water suppliers downgradient of the property for service area information, including plans for future water supply well development and service area expansion. If all of the requirements are met, the Department may determine that the aquifer is not used for drinking water or agricultural purposes. The remediator may use the MSCs for groundwater in aquifers not used for drinking water or agricultural purposes in Tables 1 and 2 of Appendix A to the regulations if the nonuse aquifer determination is made. In some cases, there may be a significant lapse in time between the nonuse aquifer determination approval and the submission of the final report. It is the intent of DEP to ensure that the nonuse aquifer conditions are still representative when the final report is submitted to the Department. Therefore, at the time the final report is submitted to the Department for sites which have a nonuse aquifer determination approval, the DEP may require basic assessment of any changes which may have taken place since the nonuse aquifer determination approval was granted. This assessment would be similar to that applied under the postremediation care plan described below.

A postremediation care plan is required to provide reasonable confidence that the appropriate geographic area continues to meet the conditions of 25 Pa. Code § 250.303(c) if a final report has been submitted to the Department which includes the use of a nonuse aquifer area. Typical elements of such a postremediation care plan, which are relevant to the nonuse aquifer status, would include review of Department of Conservation and Natural Resources (DCNR) records to see if any well drilling reports have been received for the area included in the nonuse aquifer determination, inquiry to the water supplier of the area to determine if properties are still being billed for water, or communication with the municipalities to understand what changes may have taken place which may have an effect on the water use patterns in the area. The ecological screening process and the demonstration of compliance with surface water quality standards continue to apply in the area where the aquifer is determined not to be used for drinking water or agricultural purposes. Furthermore, as described in 25 Pa. Code § 250.303(d)(3), an environmental covenant should include the requirements of the postremediation care plan. This will ensure that subsequent landowners are aware of their responsibilities for postremediation care and monitoring. The postremediation care obligation will continue only until the property owner demonstrates to the Department, by fate and transport analysis, that the MSC for groundwater in aquifers used or currently planned for use is not exceeded at the property boundary and all points downgradient therefrom.

iv) Request for Certification of a Nonuse Aquifer Area Initiated by a Local Government

This option would be used by municipal authorities and political subdivisions which desire to receive certification that a given geographic area meets the conditions of 25 Pa. Code § 250.303(c) (i.e., nonuse aquifer

area conditions) where no specific property to be remediated has been identified. These conditions are based on 25 Pa. Code § 250.303(f), which requires an ordinance prohibiting groundwater use and requires every property to be connected to the public water supply.

v) Example

The following figures illustrate the process for determining the area in which the conditions of 25 Pa. Code § 250.303(c) must be met for a site to qualify for a nonuse aquifer designation. The requirements of 25 Pa. Code § 250.303(c) must be met "within the site on the property and within a radius of 1,000 feet downgradient of the points of compliance, plus any additional areas to which the contamination has migrated and might reasonably be expected to migrate."

Figure II-13 shows this area for an idealized site with a property line parallel to the ground water contour. Note that the area includes, first, all points within 1,000 feet of all compliance points that are at a lower groundwater elevation (downgradient) of the property line compliance point itself, plus any additional area to which the plume has migrated or may be expected to migrate, as determined by site characterization and fate and transport analysis.

Figure II-14 shows the screening area for a site where the site characterization has determined that there is convergent groundwater flow. In this case the screening area is somewhat smaller than in the first figure because the area 1,000 feet downgradient (lower groundwater elevation) from the compliance points is smaller.

Figure II-15 shows the screening area for an idealized site where the site characterization has determined there is divergent groundwater flow. In this case the screening area is somewhat larger than the other figures because the area 1,000 feet downgradient (lower groundwater elevation) from the compliance points is larger.

In areas with complex groundwater flow or other special features, the Department should be consulted to determine the appropriate screening area prior to conducting the required surveys.

e) Ecological Screening

All sites remediated to the SHS must be screened for impacts to the ecological receptors identified in 25 Pa. Code § 250.311(a). The presence of threatened or endangered species as, designated by the U.S. Fish and Wildlife Service under the Endangered Species Act, requires that all requirements of that Act be met in addition to the requirements of 25 Pa. Code § 250.311. The remediator has the option of either remediating the site to one-tenth of the applicable Statewide health MSCs from Tables 3 and 4 of Appendix A to the regulations, as described in 25 Pa. Code § 250.311(b), or using the ecological screening process described

in 25 Pa. Code § 250.311 (b)-(e) and illustrated in Figure II-16. The option of remediating to one-tenth the value in Tables 3 and 4 is not available if constituents of potential ecological concern (CPECs), listed in Chapter 250, Table 8 of Appendix A, are present on the site. This choice, and the results of the screening process, if used, should be documented in the final report.

The objective of the ecological screening procedure is to quickly evaluate whether surface soils or sediments at a site have the potential to pose substantial ecological impact or impacts requiring further evaluation. The site screening procedure defines substantial impact as the potential for constituents detected onsite to cause a greater than 20% change in abundance of species of concern compared to an appropriate reference area, or a greater than 50% change in the extent or diversity of a habitat of concern compared to an appropriate reference area (Suter, 1993; Suter et al., 1995; U.S. EPA, 1989). Individuals of endangered or threatened species and exceptional value wetlands are protected regardless of the percentage of change in the abundance of species or in the extent or diversity of habitat. The goal of the screening procedure is to minimize, to the extent practicable, the number of sites which require detailed ecological risk assessment, while remaining protective of the environment.

The key elements of the screening procedure include the presence of light petroleum product constituents; the size of the site; the presence or absence of CPECs on the site; the presence or absence of species of concern or habitats of concern; and the presence or absence of completed exposure pathways, taking into account the current or planned future use of the site. The ecological screening process is described in this manual as part of the site characterization process because the information required to evaluate a site for ecological receptors is most efficiently collected at the same time as other site characterization data. A more detailed description of the rationale behind each of the steps in the ecological screen is available from the LRP website.

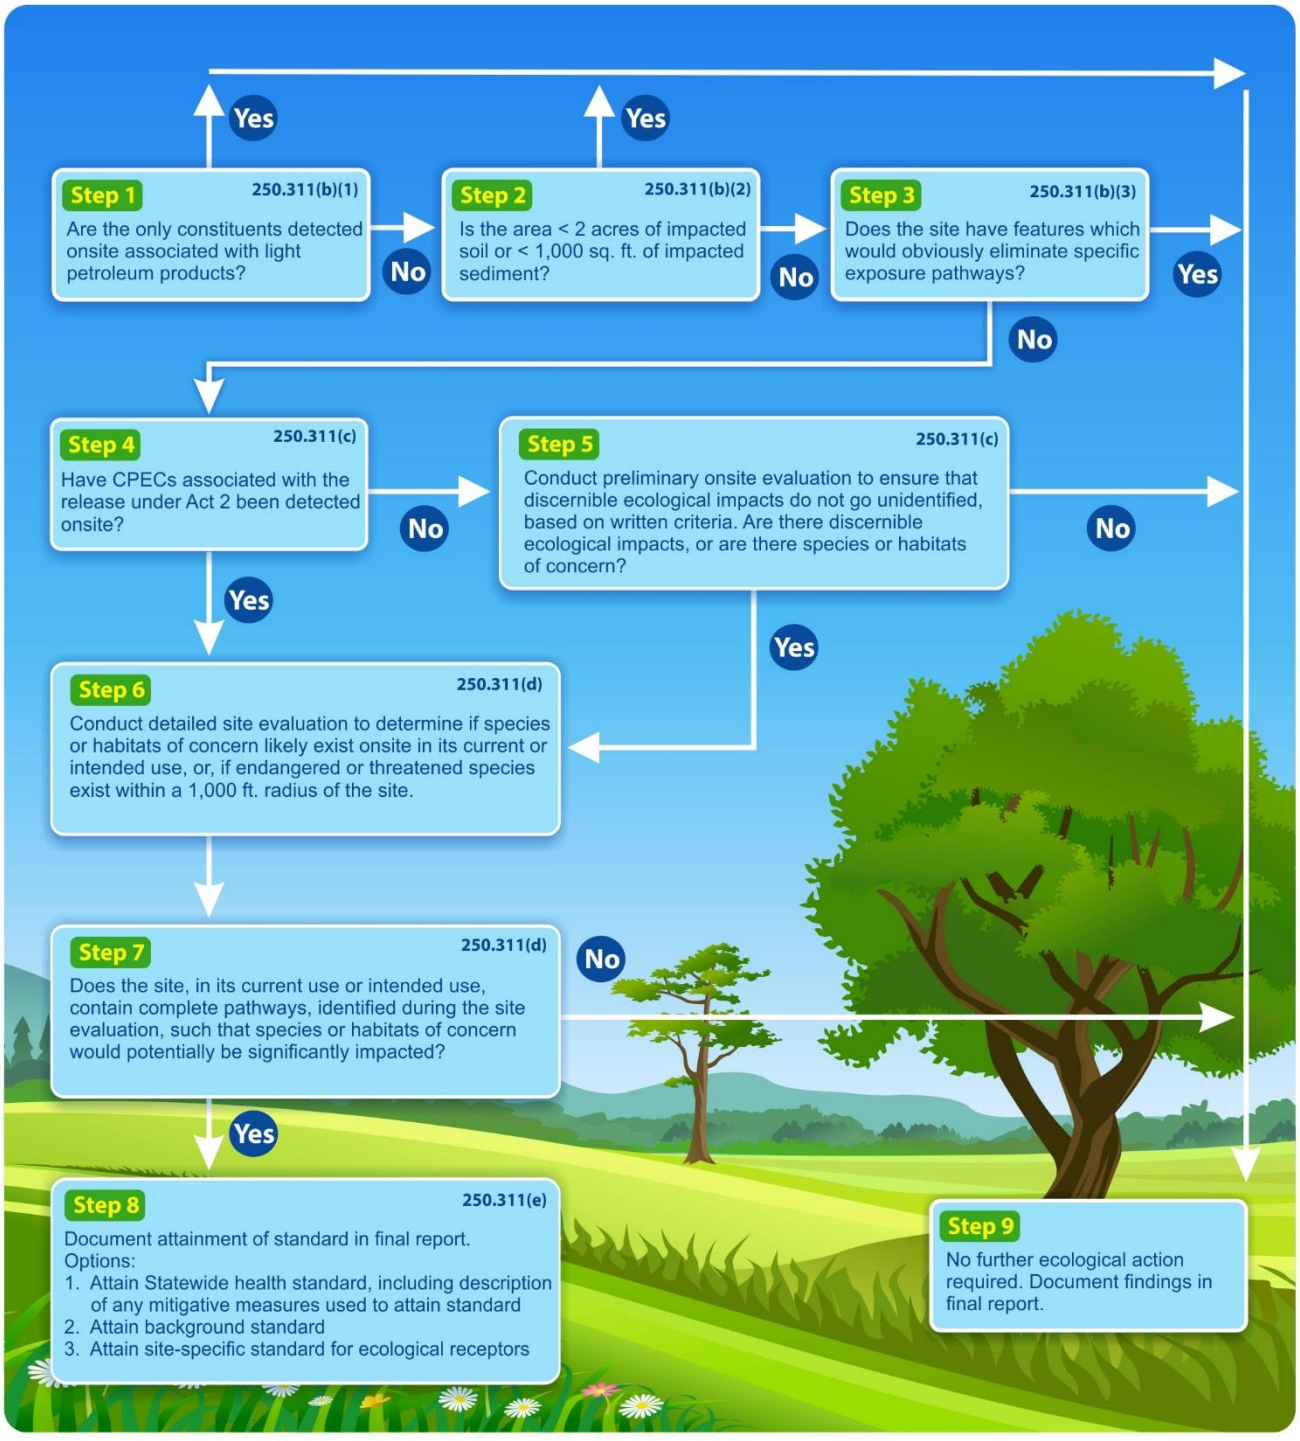
Figure II-16: Ecological Screening Decision Tree



Note: Figure must be used in conjunction with the text. Reference Section II.B.2.e)

Regardless of the outcome of the ecological screening, the results are documented in a written report. It is important to note that if all of the first three steps are not met, i.e., there is contamination other than light petroleum products; the impacted area of surface soil is equal to or greater than 2 acres, the impacted area of sediments is greater than or equal to 1000 square feet; and all pathways are not obviously eliminated, completion of the site ecological screening process requires an onsite evaluation. Using a streamlined set of guidelines, this onsite evaluation is a critical component of the means of identifying those sites that may pose substantial ecological impacts, and of documenting the lack of ecological impacts at other sites. Without such a site evaluation, a weight of evidence-based evaluation cannot be achieved, as required by EPA guidance (e.g., EPA's Framework for Ecological Risk Assessment, 1992) and ASTM standards (ASTM Designation: E1706-95). In addition, this screening procedure is consistent with the initial steps of EPA's ecological risk assessment guidelines for contaminated sites (U.S. EPA, 1997). The remainder of this section discusses each of the steps of the ecological screening procedure in more detail.

i) Step 1: Presence of Light Petroleum Product Constituents

The first step in the site ecological screening process is to determine whether the constituents present in surface soils (soils at a depth of up to two feet) or sediments are related only to light petroleum products (i.e., gasoline, jet fuel A, kerosene, #2 fuel oil/diesel fuel), which have relatively low polyaromatic hydrocarbon (PAH) content (American Society for Testing and Materials (ASTM) Designation: E1739-95). If light petroleum product constituents (including benzene, toluene, ethylbenzene, and xylenes (BTEX)) are the only constituents detected onsite, then the screening process moves to Step 9 (Final Report - No Further Ecological Evaluation Required). If constituents in addition to or other than light petroleum product constituents are present, the screening process continues to Step 2 (Site Size).

The purpose of this step is to eliminate from further evaluation those sites at which the only detected constituents are residual compounds from a release of light petroleum products. In general, remediation of light petroleum product release sites to prevent substantial ecological impacts is not required because the SHSs for these compounds are generally protective of ecological receptors.

ii) Step 2: Site Size

The second step in the ecological screening process is determining the area of exposed and contaminated surface soil (soils at a depth of up to two feet) and sediments that are of potential ecological concern. The minimum areas are 2 acres of exposed and contaminated surface soil, and 1,000 square feet of contaminated sediment.

Sediments are those mineral and organic materials situated beneath an aqueous layer for durations sufficient to permit development of benthic

assemblages. Indicators of benthic assemblages would include macroscopic algae, aquatic invertebrates, or aquatic plants. The aqueous layer may be static, as in lakes, ponds, or other water-covered surface depressions greater than or equal to 1,000 square feet but necessarily contiguous (excluding permitted open water management units), or flowing, as in rivers and streams located on a site (U.S. EPA, 1993b; U.S. EPA, 1991a).

If a site exceeds these specified minimum areas, then the screening process continues to Step 3 (Obvious Pathway Elimination). If the area of the site is smaller than the specified minimum areas, then the screening process moves to Step 9 (Final Report - No Further Ecological Evaluation Required).

iii) Step 3: Obvious Pathway Elimination

The third step accounts for those sites where features such as buildings, paving, or other development of the site are sufficiently extensive as to eliminate specific exposure pathways to ecological receptors. This primarily applies to sites in heavily industrialized or otherwise developed areas such that habitats or species of concern could not occur onsite or within a reasonable distance. Any site with features that obviously eliminate exposure pathways will drop out of the screening process at this point and proceed to Step 9 (Final Report - No Further Ecological Evaluation Required).

iv) Step 4: Presence of Constituents of Potential Ecological Concern

The fourth step in the ecological screening process is the determination of whether any of the constituents detected at the site and related to releases at the site are considered to be CPECs. CPECs are identified in Chapter 250, Table 8 of Appendix A..

In this and the following step, available site information would be reviewed to determine if CPECs are likely to have been released into the environment. If CPECs are not detected at the site, then the screening process continues to Step 5 (Preliminary Onsite Evaluation). If one or more CPECs, either individually or in combination, are detected at the site, then the screening process moves to Step 6 (Detailed Onsite Evaluation and Identification of Species and Habitats of Concern).

The ecological evaluation process that has been developed includes additional evaluation criteria for sites where CPECs are not found. Step 5 is an evaluation of adverse chemical effects that may result from regulated substances other than CPECs, and as such reduces the probability that substantive adverse environmental impacts will go undetected. Also, surface water regulations and standards will remain applicable to those sites, adding to the overall protection of the environment at any site, as

will other regulations applicable to species of concern, such as the Endangered Species Act.

v) Step 5: Preliminary Onsite Evaluation

Prior to performing onsite evaluations, it is recommended that remediators perform internet-based habitat and species of concern searches using online tools such as the Pennsylvania Natural Heritage Program's PNDI and the U.S. Fish and Wildlife Service's National Wetlands Inventory (NWI) mapper. The fifth step of the site ecological screening process is a preliminary onsite evaluation, to be conducted by a qualified environmental scientist (common practice would use a person with a bachelor's degree in an environmental science field and 5 years of experience in an environmental field), using the criteria presented in this guidance. If, after conducting the preliminary onsite evaluation, the qualified environmental scientist determines that substantial ecological impacts are not probable or evident based on the weight of evidence available for the site, the screening process moves to Step 9 (Final Report – No Further Ecological Evaluation Required). It must also document the presence of any endangered or threatened species within a radius of 2,500 ft. of the site or exceptional value wetlands onsite. If after conducting the preliminary onsite evaluation, the qualified environmental scientist determines that substantial ecological impacts or impacts requiring further evaluation are or may be present, the screening process continues to Step 6 (Detailed Onsite Evaluation and Identification of Species and Habitats of Concern).

The objective of the ecological evaluation conducted during the preliminary onsite evaluation is to ensure that ecological impacts resulting from regulated substances which are not CPECs are detected. The preliminary onsite evaluation involves three steps:

1. Review of readily available site information, including the operational history, chemicals used, and probable sources of releases of regulated substances; and, environmental setting with emphasis on physical, chemical and biological factors that would influence the nature and extent of contamination.

2. A preliminary onsite investigation to identify physical and habitat features of the area and to identify nearby reference areas without contamination (if available) that are outside of the probable site (area of contamination associated with a particular release). The following should be noted during the evaluation:

    - signs of stressed or dead vegetation (e.g., chlorotic vegetation),

    - discolored soil, sediment or water (i.e., a sheen),

- presence of non-native materials in sediments resulting from seeps or other discharges emanating from the subject site,
- presence of deformed organisms (if encountered),
- presence of exceptional value wetlands,
- presence of federally designated threatened or endangered species.

3. Preparation of a brief written summary of findings including sketches of the suspected area of contamination and reference areas. To the extent practicable, differences of greater than 50% in the density of species of concern or in the diversity and extent of habitats of concern shall be regarded as potentially substantive (Suter, et al., 1995; U.S. EPA, 1989). However, the presence of federally endangered or threatened species within a 2,500-ft. radius of the site or exceptional value wetlands onsite would trigger further evaluation.

Based on all of the information collected as part of the preliminary onsite evaluation, the investigator makes a determination as to whether substantial ecological impacts exist or are probable even though CPECs were not detected on the site. The conclusion, which documents the weight of evidence from the onsite evaluation, is summarized in bulleted format.

vi) Step 6: Detailed Onsite Evaluation and Identification of Species and Habitats of Concern

The sixth step in the ecological screening process is a detailed onsite evaluation and a determination of whether species or habitats of concern exist on the site or, for endangered and threatened species, if those species exist on the site or within a 2,500-foot radius of the border of the site in its current or intended use or if exceptional value wetlands exist onsite. Species of concern are identified in the PNDI on the PA DCNR webpage. If, during the detailed onsite evaluation, no species or habitats of concern are identified on the site, no threatened or endangered species exist within a 2,500-ft. radius of the border of the site, and no exceptional value wetlands occur onsite, the screening process moves to Step 9 (Final Report – No Further Ecological Evaluation Required). If species or habitats of concern are identified on the site, the screening process continues to Step 7 (Identification of Completed Exposure Pathways).

Identification of species and habitats of concern requires a detailed onsite evaluation. Common practice is to have a certified ecologist, or a trained environmental biologist perform this evaluation. At a minimum, the person conducting the detailed onsite evaluation should be a certified

ecologist or hold a college degree in ecology or environmental science and have at least 5 years of experience conducting ecological field work and risk assessments.

The objective of the detailed onsite evaluation is to identify species or habitats of concern and to make observations that will permit a determination of whether complete exposure pathways are present at the site, as required by Step 7 of the ecological screening process. If the detailed onsite evaluation is being conducted as the result of potential impacts being identified during a preliminary onsite evaluation, the information from the preliminary onsite evaluation may be used at this stage where the information requested duplicates efforts of the previous evaluation. However, depending on the nature of the particular site, it may be necessary to supplement this previously developed information. The detailed onsite evaluation has the following components:

1. Review of readily available site background information including:

    - operational history, chemicals used, and probable sources of releases of CPECs,

    - environmental setting with emphasis on physical, chemical and biological factors that would influence the nature and extent of contamination, and

    - readily available literature and other relevant documents related to recognition of species and habitats of concern, including endangered and threatened species.

2. The qualified investigator shall conduct the following evaluation:

    - complete an onsite investigation to identify physical and habitat features of the area, then identify nearby reference areas, if available, which are outside of the probable site (area of contamination associated with a particular property),

    - qualitatively evaluate whether species or habitats of concern are present at the site and in the reference area, and

    - in comparison to reference areas, the qualified investigator shall evaluate the following to the extent that they can be readily evaluated at a site:

        – signs of stressed or dead vegetation (e.g., chlorotic vegetation),

        – discolored soil, sediment, or water,

- presence of non-native materials in sediments resulting from seeps or other discharges emanating from the subject property,

- community composition differences readily distinguished by U.S. EPA protocols such as the Rapid Bioassessment procedures (U.S. EPA, 1989),

- absence of biota (especially keystone species and ecological dominants) compared with similar areas of the same system,

- presence of non-native or exotic species compared with reference areas (e.g., Phragmites),

- presence of deformed organisms (if encountered), and

- potential for residual contamination of habitats of concern and areas utilized by species of concern.

3. A brief written summary of findings including sketches of the suspected area of contamination and reference areas. Differences of greater than 20% in the density of species of concern or greater than 50% in the diversity or the extent of habitats of concern shall be regarded as potentially substantive (Suter, 1993; Suter, et al., 1995; U.S. EPA, 1989). However, the presence of exceptional value wetlands or federally designated endangered or threatened species would trigger further evaluation.

4. The site ecological screening process defines as species of concern those that have been designated as either of special concern, endangered, threatened or candidate by the Pennsylvania Game Commission, Pennsylvania Fish & Boat Commission, and the DCNR Bureau of Forestry. Links to current lists of such species are summarized on their respective webpages.

5. The ecological screening process defines as habitats of concern:

   - typical wetlands with identifiable function and value, except for exceptional value wetlands, as defined by DCNR,

   - breeding areas for species of concern,

   - migratory stopover areas for species of concern (e.g., migrant shorebirds, raptors or passerines),

- wintering areas for species of concern,
- habitat for State endangered plant and animal species,
- Federal, State, and local parks and wilderness areas,
- areas designated1 as wild, scenic, recreational, and
- areas otherwise designated as critical or of concern by the Pennsylvania Game Commission, Pennsylvania Fish & Boat Commission, and DCNR.

vii) Step 7: Identification of Completed Exposure Pathways

The seventh step in the ecological screening process is a determination of whether a completed exposure pathway from CPECs to species or habitats of concern exists at the site in its current or intended use. The existence of a completed exposure pathway[2] is determined during the detailed onsite evaluation, as described above for Step 6. Note that the CPECs in soil beneath a paved parking lot or below the root zone (top two feet) are not accessible to most species and habitats of concern, and therefore this pathway is classified as incomplete. If a complete pathway exists at the site, then the screening process moves to Step 8 (Attainment of Standard and Mitigative Measures). If no complete exposure pathways are identified during the detailed site evaluation, then the screening process continues to Step 9 (Final Report – No Further Ecological Evaluation Required).

viii) Step 8: Attainment of Standard and Mitigative Measures

If the results of Steps 1 through 7 above do not result in the site being eliminated from further ecological consideration, the person conducting the remediation must demonstrate one of the following:

- attainment of the SHS is protective of ecological receptors,
- if the remediator cannot demonstrate that the SHS MSCs are protective of ecological receptors, the person shall demonstrate either that the postremedy use will result in the elimination of all complete exposure pathways at the time of the final report, or in accordance with a postremediation care plan, or that mitigative measures have been implemented and a postremediation care program has been instituted,

[1] as defined by guidance.

[2] Exposure pathway - the course a regulated substance(s) takes from the source area(s) to an exposed organism of a species of concern including absorption or intake into the organism. Each complete exposure pathway must include a source or release from a source, a point of exposure, and an exposure route into the organism. The mere presence of a regulated substance in the proximity of a receptor does not constitute a completed pathway. The receptor of concern must contact the regulated substance in such a way that there is high probability that the chemical is absorbed into the organism (ASTM E1739-95; modified to accommodate provisions of Act 2).

- attainment of the background standard, or

- that the procedures of 25 Pa. Code § 250.402(c) and 250.409 and Sections II.B.3 and III.H. of this manual have been followed to demonstrate attainment of a site-specific standard for protection of ecological receptors.

Mitigative measures that may be used to demonstrate attainment of the SHS are identified in Section 25 Pa. Code 250.311(f). These mitigative measures may only be used if no exceptional value wetlands have been identified by the screening process, and no state or federal laws or regulations prohibit the destruction of the habitats or species identified in the screening process.

The following mitigative measures may be used, and in the indicated order of preference:

- Restoration onsite of species and habitats identified in the screening process.

- Replacement onsite of species and habitats identified in the screening process.

- Replacement on an area adjacent to the site of species and habitats identified in the screening process.

- Replacement at a location within the municipality where the site is located of species and habitats identified in the screening process.

The Department shall review and approve any proposed mitigative measures prior to implementation to ensure that the intended use of the site minimizes the impact to ecological receptors identified in the screening process. In addition, the postremediation care plan requirements in 25 Pa. Code § 250.312(e) or 250.411(f) and Section III.D of this manual must be implemented.

ix) Step 9: Final Report - No Further Ecological Evaluation Required

The ninth step of the ecological screening process requires that a report be written documenting the findings of the completed steps of the screening process, the basis for the conclusion that a substantial ecological impact does not exist, and that further ecological evaluation is not required. The conclusion that substantial ecological impact does not exist is based on one of the following:

- The presence of light petroleum-related constituents only (findings from Step 1).

- The area of impacted surface soil or sediment is less than the minimum size criterion (findings from Steps 1 and 2).

- All pathways are obviously eliminated by specific site features (findings from Steps 1 through 3).

- No CPECs are present onsite and the preliminary site evaluation indicates that substantial ecological impacts have not been overlooked (findings from Steps 1 through 5).

- No species or habitats of concern, threatened or endangered species, or exceptional value wetlands were identified on the site during the detailed site evaluation (findings from Steps 1 through 6).

- No complete exposure pathways from CPECs or other contaminants onsite to species or habitats of concern were identified during the detailed site evaluation (findings from Steps 1 through 7).

- Complete exposure pathways from CPECs or other contaminants onsite to species or habitats of concern were identified, but no significant impacts were observed during the detailed site evaluation.

f) Final Report Requirements for the Statewide Health Standard

To receive the liability protection afforded under Chapter 5 of Act 2 for sites remediated under the SHS, the remediator shall submit a final report to the Department which documents attainment of the standard. Section 250.312 of the regulations discusses final report requirements.

The final report shall be prepared in accordance with scientifically recognized principles, standards, and procedures. The report should present a thorough understanding of the site conditions. It should provide a detailed discussion on the areas for concern and a conceptual site model based on the results of the site work. The report should support interpretations and conclusions with data collected during all of the investigations at the site. The level of detail in the investigation and the methods selected shall sufficiently define the rate, extent and movement of contaminants to assure continued attainment of the remediation standard. All interpretations of geologic and hydrogeologic data shall be prepared by a professional geologist licensed in Pennsylvania.

Two copies of the final report should be submitted to the Department for review. One should be a paper copy, and the other copy may be submitted in another format (CD, flash drive, etc.). The final report must include the information in Table II-2, and the organization shown in the following outline is preferred:

Table II-2: Suggested Outline for a Final Report under the Statewide Health Standard

I. Final Report Summary

The final report summary should be a copy of the electronic form submitted to the Department.

II. Site Description

Describe the site in sufficient detail to give an overall view of the site (Section II.B.2(f)(ii)).

III. Site Characterization

Document current conditions at the site (§ 250.204 of the regulations and Section II.B.2(f)(iii)).

IV. Statewide Health Standard

Describe how the SHS was established (Section II.B.2(f)(iv)).

V. Ecological Screening

Provide the results of the Ecological Screen described in § 250.311 of the regulations and Section II.B.2(e).

VI. Remediation

Describe the remedial methodologies used to attain the selected standard (Section II.B.2(f)(vi)).

VII. Attainment

A. Soil SHS

B. Groundwater SHS

C. Diffuse groundwater flow into surface water

D. Spring flow into surface water

Sections A, B, C and D describe the statistical methods used to demonstrate attainment of the standard (Section II.B.2(f)(vii)).

VIII. Fate and Transport Analysis

Describe the Fate and Transport analyses used and results and conclusions (Section II.B.2(f)(viii)).

IX. Postremediation Care Plan

This section is included only if necessary. It describes the engineering and institutional controls necessary to attain or maintain the standard (Section II.B.2(f)(ix)).

X. References

(Section II.B.2(f)(x))

XI. Attachments

(Section II.B.2(f)(xi))

XII. Signatures

(Section II.B.2(f)(xii))

i) Summary

The Final Report Summary form is to be filled in and submitted to the Department electronically. The summary submitted with the final report should be a copy of that completed electronic form.

ii) Site Description

Provide a description of the site in sufficient detail to give the reviewer an overall understanding of the site and its location and the types of operations that are currently and were formerly conducted on the site. The description should include location, physical description of the property, ownership history, site use history, and regulatory action history (past cleanups) as appropriate to the site.

iii) Site Characterization

The site characterization provides important information documenting the current conditions at the site, information required by 25 Pa. Code § 250.312, and information required for the proper demonstration of attainment. Information developed during site characterization is primarily intended to describe the nature, extent and potential for movement of all contaminants present on the site or that may have migrated from the site; the information is also used as input for developing a conceptual site model and for the fate and transport analysis. For sites where there are multiple distinct areas of contamination, the site characterization process should be applied to each area individually.

Along with a narrative, the results from the site characterization and all sampling and analysis work should be provided on map(s) illustrating, to the extent possible, the interrelationship of the following:

- All physical site characteristics.
- All groundwater, soil, sediment and other sample locations, including sample depth and contaminant concentration.
- The surveyed locations for all assessment structures (monitoring wells, soil borings, test pits, etc.). All elevations should be reported in reference to mean sea level (msl), where practical.
- Appropriate number of stratigraphic cross sections that adequately depict site stratigraphy, well locations, well depths, groundwater flow directions, equipotential lines, flow lines, hydraulic conductivity intervals and values, sampling intervals and concentrations. All elevations should be reported in reference to msl, where practical.

- Variation in potentiometric surfaces(s), potentiometric surface map(s), hydraulic gradients, and groundwater flow directions.

- All identified sources of releases.

- The extent and concentrations of contaminant plumes in all media. The horizontal and vertical extent of contaminant plumes including density and thickness of any SPL present.

- Top of bedrock contour (if encountered).

A conceptual site model should be developed and refined as information is gathered during the site characterization. The conceptual site model provides a description of the site and extent of contamination. Recommended information and data used to develop the site model include:

- The type, estimated volume, composition, and nature of the released materials, chemicals or chemical compounds (include all calculations and assumptions).

- Source(s) and extent of release(s).

- Background concentrations for constituents of concern.

- The horizontal and vertical extent of contamination.

- The portion of the horizontal and vertical extent of contamination which exceeds the selected standard.

- Affected aquifer(s) or water bearing formation(s)/member(s), hydrostratigraphic units.

- All existing and potential migration pathways.

- The estimated volume of contaminated soil and water (include all calculations and any assumptions).

For soils, include information on samples and measurements used to characterize the horizontal and vertical extent of contamination, and direction and rate of contaminant movement based on factors in the soil and the contaminant which affect migration. Soil and boring descriptions should be included as an attachment.

For groundwater, include information on samples and measurements used to characterize the horizontal and vertical extent of contamination and direction and velocity of contaminant movement based on factors of the groundwater and the contaminant(s) which affect migration. Geologic

boring descriptions and as-built drawings of wells should be included as an attachment. Text, tables, graphics, figures, maps, and cross sections, as appropriate, can be utilized to describe the nature, location, and composition of the regulated substances at the site. Providing the data in an appropriate format will expedite the review of the report.

iv) Selection of the Applicable Statewide Health Standard

Documentation of the basis for selecting residential or nonresidential standards and for selecting the applicable MSCs according to the procedure in Section II.B.2(c) of this manual should be included in this section of the final report.

If the site is in an area where groundwater is not used or planned to be used for drinking water or agricultural purposes, provide the following documentation:

- That no groundwater derived from wells or springs is used or currently planned to be used for drinking water or agricultural purposes.

- That all downgradient properties are connected to a community water system.

- That the nonuse area does not intersect a radius of 0.5 mile from a community water supply well and does not intersect an area designated by the Department as a Zone 2 wellhead protection area as established under Chapter 109.

- Results of the fate and transport analysis used to establish the nonuse area.

- A copy of the letter from the Department approving the use of the nonuse aquifer MSCs, as described in Section II.B.2(d) of this manual.

If the soil buffer option is used to meet the requirements of the soil to groundwater numeric value, submit the following:

- Information demonstrating that the actual site soil column thickness below the contaminated soil is at least the thickness identified in Tables 3B and 4B of Appendix A to the regulations. This information should be taken from soil sample borings conducted during the site characterization.

- Laboratory analyses demonstrating that the contaminant concentrations in the entire soil column below the contaminated zone do not exceed either the limit related to the PQL or background.

- The boring logs and all other data presented in appropriate maps, cross sections, figures, and tables.

If an equivalency demonstration is used to meet the requirements of the soil-to-groundwater numeric value, submit the following:

- Information describing the actual site soil column below the contaminated soil. This information should be taken from soil sample borings conducted during the site characterization.

- Information, including laboratory analyses, gathered during the site characterization that demonstrates that the groundwater is not impacted at levels exceeding either the groundwater MSC or background.

- The boring logs and all other data presented in appropriate maps, cross sections, figures, and tables.

- Sampling data, in a tabular format, that shows no exceedance for eight quarters of groundwater MSCs or the background standard, in accordance with 25 Pa. Code § 250.308(d)(2).

- Results of the fate and transport analysis that demonstrate that the regulated substance(s) will not migrate to bedrock or the groundwater within 30 years at concentrations exceeding the greater of the groundwater MSC or background in groundwater as the end point in soil pore water directly under the site.

v) Ecological Screening

Provide documentation of the implementation of the ecological screen described in 25 Pa. Code § 250.311 and Section II.B.2(e) of this manual.

vi) Remediation

Remediation should be planned to remediate all areas to the selected standard.

Provide a description of the remedial methodologies used to remediate that portion of the contamination which exceeds the selected standard as determined by the site characterization. Examples of the types of information typically included in this section include:

- Identification of areas remediated based on results of site characterization.

- Descriptions of treatment, removal, or decontamination procedures performed in remediation. Description of removal, what was

removed, and amount removed. Results of any treatability, bench scale, or pilot scale studies or other data collected to support the remedial action(s).

- Description of treatment technologies.

- Description of the methodology and analytical results used to direct the remediation and determine the cessation of remediation. This description should document how the remediator determined that remediation was performed to address all areas known to exceed the standard.

- Documentation of handling of remediation wastes in accordance with applicable regulations.

- Specific characteristics of the site that affected the implementation or effectiveness of the remedial action including such characteristics as topography, geology, depth of bedrock, potentiometric surfaces, and the existence of utilities.

- All other site information relevant to the conceptual design, construction, or operation of the remedial action.

In addition to the above, this section should also include the calculation of the mass of contaminants addressed during the remediation of soil and/or groundwater, using the methodology in Section III.C.

Remediation of surface water will typically be accomplished by eliminating or reducing the discharge of regulated substances into surface water to the level where surface water quality standards are being achieved. Given that the usual source of regulated substance discharge to surface water will be via non-point source groundwater discharge, the measures necessary to attain the surface water standard should be incorporated into the design of any groundwater remediation system.

Abatement of air quality discharges associated with the remediation (e.g., vapor discharges from air stripping towers) shall be handled in accordance with the applicable air quality statutes and regulations.

During the implementation of any remediation plan, appropriate record keeping must be performed to provide ample documentation of the remedial actions taken, any changes made from the preplanned activities, and any sampling performed as field controls during implementation.

vii) Attainment

Provide documentation that the remediation has attained the selected standard at the POC and that the standard will not be violated in the future as a result of remaining contamination. The demonstration of attainment,

like the site characterization, should be applied to each distinct area of contamination. Attainment must meet the requirements of Chapter 250 Subchapter G (Demonstration of Attainment).

If the Statewide health standard is numerically less than the background standard, the remediator may elect the background standard, and attainment of the background standard should be demonstrated according to Section 302 of Act 2.

(a) Point of Compliance

(i) Groundwater

The POC for groundwater under SHS is the property boundary. Under certain circumstances the POC may be moved, as described below. Prior approval from the Department to move the POC is required.

The remediator may request the movement of the POC for situations described in § 250.302(a) of the regulations. If any of those conditions exist, the remediator must request, in writing, that the Department approve moving the POC. The Department will respond in writing to the request, and the response must be obtained before the adjusted POC may be used and the final report submitted.

For substances with a Secondary Maximum Contaminant Level (SMCL) established by EPA under the National Secondary Drinking Water Regulations, the remediator may request that the POC be moved for those substances with SMCLs. The Department will consider moving the POC in a range anywhere from the property boundary up to the point of use. Therefore, demonstration of attainment at a site may involve POCs for SMCLs which are different from the POCs applicable to the other identified regulated substances.

(ii) Soil

The POC for soil is the entire area of contamination. Demonstration of attainment of the appropriate standard is to be made in the entire volume shown in the site characterization to be contaminated by regulated substances at concentrations exceeding the SHS. Some sites may have different SHS values for varying depths or conditions of soil. For example, on a nonresidential site, if the soil-to-groundwater numeric value is lower than the direct contact number, there may be one standard for the 0-2 foot interval, another for the 2-15 foot interval, and a third for the soil at

depths greater than 15 feet. In addition, if any of these depths are in the periodically saturated zone, the appropriate standard may be different because of the requirement for reducing the generic value of the soil-to-groundwater numeric value by a factor of 10 (see Section II.B.2(c)(ii)(a)). For the purpose of demonstrating attainment, the saturated zone is considered to extend below the seasonal high water table level.

(iii) Spring flow into surface water

Unless an NPDES permit is required for purposes of complying with surface water quality in a spring, the POC is the point of first designated or existing use as defined in 25 Pa. Code §§ 93.1, 93.4, and 93.9. This could mean right by the spring itself or some point downstream from the spring discharge. Determining the point of first designated use is necessary because it establishes the point where Chapter 93 water quality standards apply.

Technical guidance to determine point of first use is found in *Policy and Procedure for Evaluating Wastewater Discharges to Intermittent and Ephemeral Streams, Drainage Channels and Swales, and Storm Sewers,* DEP document # 391-2000-014, revised April 2008. In essence this guidance relies on biological techniques to determine the first downstream point where aquatic life can be documented. It applies to both perennial and intermittent streams with definable bed and banks, but not to ephemeral streams, that is, areas of overland runoff which occur only during or immediately following rainfall events and where there is no defined stream channel and stream substrate.

(b) Statistical Tests

Attainment tests appropriate for SHS are described in 25 Pa. Code § 250.707(b) and in Section III.B of this manual and include:

- The 75%/10x rule for soil and groundwater at the POC, and the 75%/2x rule for groundwater off the property.
- For groundwater, no exceedance of SHS.
- The 95% upper confidence limit (UCL) test.
- For sites that are remediated without prior full site characterization, a “no exceedance” of SHS.

- A method that meets the performance requirements of 25 Pa. Code § 250.707(d).

If the 75%/10x rule is not used, appropriate statistical tests must be employed to demonstrate attainment of SHS. The following information should be documented in a final report:

- Description of the statistical method, and the underlying assumptions of the method.

- Documentation showing that the sample data set meets the underlying assumptions of the method and explaining why the method is appropriate to apply to the data.

- Specification of false positive rates.

- Documentation of input and output data for the statistical test, presented in table and figures, or both, as appropriate; and identify, by media, contamination levels remaining onsite.

- An interpretation and conclusion of the statistical test.

In addition to the attainment tests described above, the remediator must demonstrate, for groundwater remediated to the SHS, that the standard has been attained and that it will continue to be attained in the future as indicated by a fate and transport analysis.

In demonstrating attainment of SHS, concentrations of regulated substances are not required to be less than the limit related to the PQL for that substance as provided for in 25 Pa. Code § 250.4 and 250.701(c) and as listed in Section III.F of this manual. Where the plume of contamination currently impacts or may impact properties with different land use categories (i.e., residential and nonresidential), the SHS appropriate for the impacted property must be attained and maintained. For example, where a plume of contamination emanating from a nonresidential property adjoins a residential property that will be impacted by the plume, the nonresidential SHS must be attained and maintained at the downgradient boundary of the nonresidential property (see 25 Pa. Code § 250.702), and the residential SHS applies at the residential property. Demonstration that the appropriate standard will be attained and maintained must be demonstrated by a combination of sampling and fate and transport analysis.

In demonstrating attainment of the SHS in groundwater in aquifers not currently used or planned to be used, the remediator must show that the nonuse aquifer MSC has been met at the POC using the appropriate tests for demonstrating attainment described in 25 Pa.

Code § 250.707(b)(2) and further described in Section III.B of this manual. In addition, the requirements of 25 Pa. Code § 250.705 must be met regarding the use of a fate and transport analysis to show that the MSC for groundwater in aquifers used or currently planned to be used will not be exceeded at and beyond all points on a radius of 1,000 feet downgradient from the property boundary within 30 years. This fate and transport analysis should meet the requirements specified in Section III.A of this manual.

(i) 75%/10x rule

The 75%/10x rule is a statistical ad hoc rule that determines if the true site median concentration is below the cleanup standard. This rule requires that 75% of the samples collected for demonstration of attainment be equal to or below the cleanup standard and that no single sample result exceeds the standard by more than ten times.

For the 75%/10x rule, the number of soil sample points required for each distinct area of contamination is specified in the Act 2 regulations and is as follows:

- For soil volumes equal to or less than 125 cubic yards, at least eight samples.
- For soil volumes up to 3,000 cubic yards, at least 12 sample points.
- For each additional volume of up to 3,000 cubic yards, an additional 12 sample points.
- Additional sampling points may be required based on site-specific conditions.

These soil volumes may be comprised of zones where different MSCs apply (e.g., depths of 0-15 feet and greater than 15 feet). For purposes of demonstrating attainment, the analysis of samples, based on their physical location by the systematic random sampling method (Section III.B), must be compared to the applicable MSC for that physical location.

To use this rule for demonstrating attainment of groundwater MSCs, eight samples from each compliance well must be obtained during eight consecutive quarters. If a shorter sampling period is to be used, there must be written approval (preapproval is recommended) from the Department and the no exceedance rule 25 Pa. Code § 250.704(d)(3) must be used rather than the 75%/10x rule.

In groundwater monitoring wells beyond the property boundary, the rule is slightly modified. The attainment criteria are that 75% of the sampling results must be below the standard, with no individual value being more than 2 times the standard (75%/2x rule). This rule would have to be met in each individual monitoring well.

(ii) 95% UCL rule

The minimum number of samples is as specified in Section III.B of this manual.

(iii) No exceedance rule

Per § 250.707(b)(1)(iii) of the regulations: for sites with a release of petroleum products, soil remediation is often conducted based on visual observations or field screening without having conducted a full site characterization. These sites may demonstrate attainment of the SHS using the procedure described in Section III.B.5(b)(i)(c) of this Manual.

viii) Fate and Transport Analysis

The Fate and Transport Section (Section III.A of this manual) provides a discussion on fate and transport analysis. The amount of detail in the fate and transport analysis may vary from a simple description to a very extensive detailed model with quantitative modeling. Whenever a model is used, the Department must be provided with the assumptions, data, and information on the model necessary for Department staff to evaluate and run the model. Any parameters used in the analysis or models used should utilize data obtained from the site during the site characterization.

Following are examples of situations when the SHS will require a fate and transport analysis/model:

- The demonstration of attainment of a standard at the POC includes a fate and transport analysis to show that the standard will not be violated in the future.

- In an area where the groundwater is not used for drinking water or agricultural purposes, a fate and transport analysis is required to show that the used aquifer MSCs are not exceeded at and beyond a radius of 1,000 feet downgradient from the property boundary within 30 years.

- In using the equivalency demonstration to meet the soil-to-groundwater numeric value, a fate and transport analysis is

required to show that soils remediated to the direct contact numeric value will not result in regulated substances migrating to groundwater at concentrations exceeding either the groundwater MSC or background.

ix) Postremediation Care Plan (if applicable)

A postremediation care plan (PRCP), which includes the information required by 25 Pa. Code § 250.204(g), must be documented in the final report in accordance with that section of the regulations if:
(1) engineering controls are needed to attain or maintain the SHS;
(2) institutional controls are needed to maintain the standard; (3) a nonuse aquifer designation has been approved for the site; (4) the fate and transport analysis indicates that the remediation standard, including the solubility limitation, may be exceeded at the POC in the future; (5) the remediation relies on natural attenuation; (6) a postremedy use is relied upon but is not implemented to eliminate complete exposure pathways to ecological receptors; or (7) mitigative measures are used. The PRCP must comply with the applicable deed acknowledgment requirements under SWMA or HSCA, Section 304(m) of Act 2, as well as the requirements of 25 Pa. Code Chapter 253 regarding the application of environmental covenants. Section III.D of this manual provides additional information regarding the application of covenants and deed notices. The plan typically should include:

- Reporting of any instance of nonattainment.
- Reporting of any measures to correct nonattainment conditions.
- Periodic reporting of monitoring, sampling and analysis as required by the Department.
- Maintenance of records at the property where the remediation is being conducted for monitoring, sampling and analysis.
- A schedule for operation and maintenance of the controls and submission of any proposed changes.

If the postremediation care plan is being used to document the continuing applicability of an approved nonuse aquifer designation, the following are required:

- Procedures for documenting that the nonuse criteria continue to be met after the original request is approved.
- Report details and schedule for submittal to the Department.

See Section III.D for the range of institutional controls available to a remediator.

The Department may ask for documentation of financial ability to implement the remedy and to maintain the postremediation care controls. Except for the special case of a nonuse aquifer designation under 25 Pa. Code § 250.303 (c) and (d), when the standard can be maintained without the controls operating, and the fate and transport analysis shows that the standard will not be exceeded in the future, the Department will approve termination of the postremediation care program.

Some remediators choose to use soil management plans (SMPs) and groundwater management plans (GWMPs) in place of PRCPs. This practice can be problematic because PRCPs are intended to be a plan to care for and maintain a remedy which utilizes engineering or institutional controls, while SMPs/GWMPs are often intended to address changes to a remedy that may occur at some point in the future. These plans are based on current waste management or water quality regulations or guidance. The Department cannot grant pre-approval of future soil or groundwater management plans since those guidances or regulations may change at some point in the future, therefore invalidating the SMP or GWMP.

Remediators should avoid using SMPs and GWMPs in place of PRCPs. They should instead have the PRCP and the environmental covenant address how to handle potential changes to a remedy. Any planned change to a remedy would require the approval of the Department at the time of the proposed change.

x) References

Any references cited in the final report.

xi) Attachments

Attachments may include but are not limited to:

- Tables – monitoring well construction summary, groundwater gauging data (including elevation and NAPL thicknesses), analytical data, historical data.
- Figures – including groundwater elevation maps, extent of NAPL, concentration data for soil/groundwater/surface water/vapor or indoor air, cross-sections.
- Monitoring well construction diagrams, boring logs, stratigraphic logs, including soil/rock characteristics.
- Sampling and analysis plan(s).
- QA and QC Plan.

- Ecological survey documentation (from PNDI).
- Well search documentation (from Pa. Geographic Information Systems Mapping Tools (PaGIS).
- Field data sheets, such as low flow purging monitoring.
- Statistical worksheets, software outputs, graphs; modeling inputs/outputs.
- Disposal documentation of soil/groundwater.
- Remediation system operation, maintenance, monitoring data; mass removal estimates.
- Before and after remediation photographs.
- Copy of municipal notification, reasonable proof of newspaper notice publication.
- Laboratory reports and any voluminous attachments may be enclosed on a CD.

xii) Signatures

If any portions of the submitted report were prepared or reviewed by or under the responsible charge of a registered professional geologist or engineer, the professional geologist or engineer in charge must sign and seal the report.

3. Site-Specific Standard

a) Introduction

The objective of the site-specific standard is to develop and evaluate detailed site information using a rigorous scientific evaluation of a remedy to provide a protective cleanup standard unique to that site. Use of this standard requires the Department's review and approval (as required by statute) of the remedial investigation report, risk assessment report (if necessary), cleanup plan (if necessary) and final report. The relationship of these steps in the site-specific assessment process is illustrated in Figure II-17. The remedial investigation report, risk assessment report, and cleanup plan may be submitted at the same time. In some cases, only a remedial investigation report and final report are required, and these can be combined (see Section II.B.3.g of this manual). In

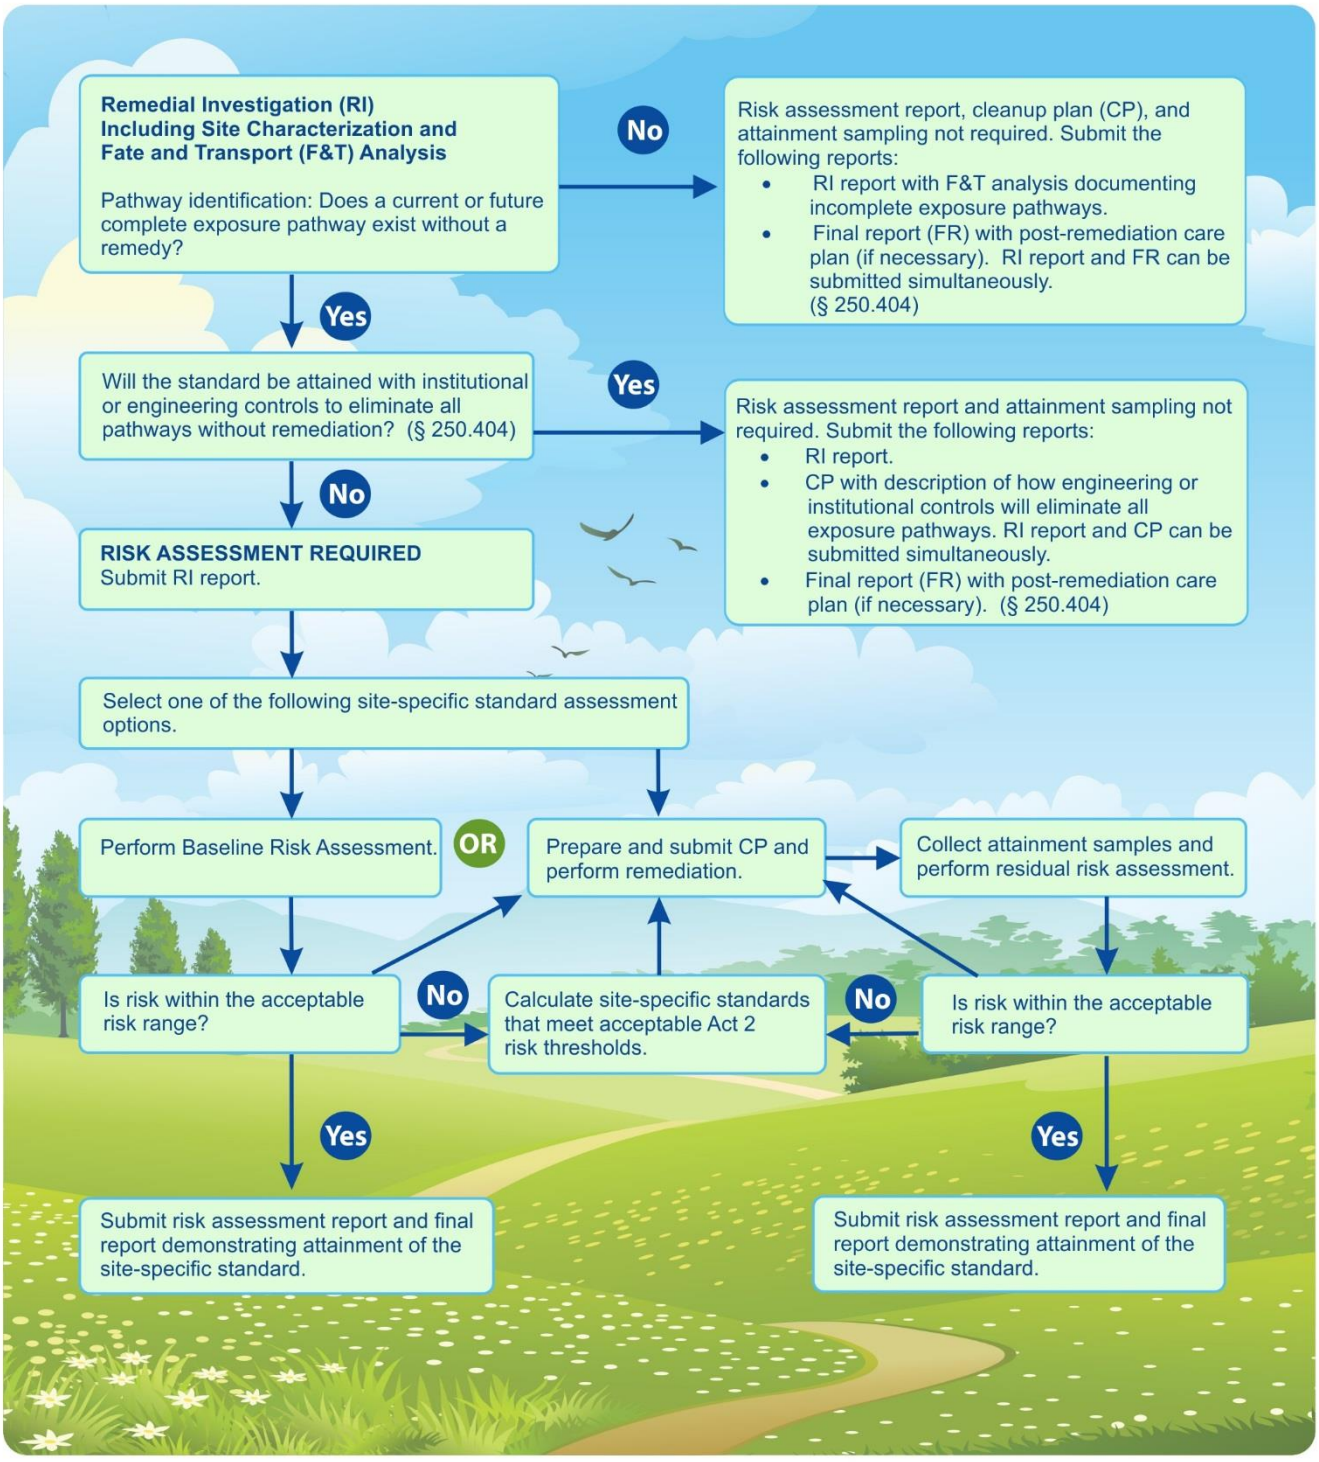
other cases (such as simple pathway elimination of all present and future exposure pathways), the risk assessment report and cleanup plan can be simplified. Note that if one part of a combined report is disapproved, then all other parts of the combined report that depend on the disapproved part will also require re-submittal, with new notices and payment of fees. For example, if a cleanup plan is disapproved, then the cleanup plan and final report must be re-submitted. However, if one part of a combined report is deficient, the remediator may have a chance to correct the deficiency in a prescribed timeframe to avoid re-submittal of notices and payment of fees.

All pathways of exposure are evaluated and the past, current, and future use of the land is considered. The resulting cleanup remedy selected to meet site-specific soil and groundwater standards may be a combination of treatment/removal efforts and engineering and institutional controls. The extent to which treatment and removal efforts are balanced with engineering and institutional controls is determined by the factors used in remedy selection. These factors are described in Section 304(j) of Act 2.

Remediators utilizing the site-specific standards must comply with the applicable deed acknowledgment requirements under the SWMA or HSCA (35 P.S. § 6026.304(m)), notice and review (35 P.S. § 6026.304(n)), and community involvement requirements (35 P.S. § 6026.304(o)) of Act 2 as well as the requirements of 25 Pa. Code Chapter 253 regarding the application of environmental covenants. Section III.D of this manual provides additional information regarding the application of covenants and deed notices.

The site-specific standard is a risk management approach. It offers more flexibility to the person than background or Statewide health standards because detailed site-specific information is collected for the evaluation. The guidance contained in Section II.A.2 of this manual provides a structure and process for this data collection or remedial investigation. The additional information does involve more time and effort to collect, and additional reviews are required by the Department under Act 2. This approach differs in that full and total use of the site may not be possible to the extent that specific land uses were presumed and engineering and institutional controls are used in the final remedy. The site-specific standard approach addresses future use limitations by environmental covenant. Also, use of the site-specific standard requires public involvement if the municipality requests to be involved in the remediation.

Figure II-17: Site-Specific Assessment Decision Tree



Note: Figure must be used in conjunction with the text. Reference Section II.B.3.

In determining soil and groundwater standards, consideration should be given to appropriate exposure factors to receptors based on land use of the site, the effectiveness of institutional or other controls placed on the future land use, potential pathways for human exposure, and appropriate statistical techniques.

b) Process Checklist for the Site-Specific Standard

A checklist for the site-specific standard is provided below and can be used to ensure administrative completeness.

☐ Submit an NIR for the site-specific standard to the Department. Also send a copy of the NIR to the municipality, publish a summary of the notice in a newspaper of general circulation serving the area in which the site is located, and provide reasonable proof of publication to the Department. Procedures are in Section II.A.3 of this manual.

☐ Notify the municipality, publish a notice in a local newspaper, and provide proof of submittal to the Department each time a remedial investigation report, risk assessment report, cleanup plan or final report is submitted to the Department. Procedures are in Section II.A.3 of this manual.

☐ Prepare and submit public involvement plan if requested by municipality. Procedures are in Section II.A.3 of this manual.

☐ Begin the remedial investigation. See Sections II.B.3(c) and II.A.4 of this manual for guidance.

☐ As an option, begin using the completeness list (see LRP web page) to help verify that all requirements have been met.

☐ Prepare and submit a remedial investigation report which includes fate and transport analysis to determine if any exposure pathways including vapor intrusion (Section IV of this manual) exist at the site. A fee of $250 is required. Reporting requirements are established by 25 Pa. Code § 250.404 and 250.408 and are described in Section II.B.3.g of this manual.

☐ Prepare and submit a risk assessment report (baseline risk assessment report and/or risk assessment report to develop site-specific standards) along with a fee of $250 to the Department. A baseline risk assessment report is not required if the Department, in its remedial investigation report or cleanup plan approval, determines that a specific remedial alternative that eliminates all pathways can be implemented to attain the site-specific standard (25 Pa. Code § 250.405(c)). A simplified risk assessment describing how the pathways are eliminated by the remedial alternative should be included in the remedial investigation report. This does not include a no-action remedial alternative. A baseline risk assessment report

is not required if no present or future exposure pathways exist, as documented by a fate and transport analysis. Risk assessment requirements are established by 25 Pa. Code §§ 250.402-407 and 250.409 and Subchapter F. Guidance is provided in Sections III.G and III.H of this manual. Reporting requirements are described in Section II.B.3(g)(v) of this manual.

☐ Prepare a cleanup plan. A cleanup plan is not required if no present or future exposure pathways exist. The cleanup plan is also not required if the approved baseline risk assessment report indicates that the site does not pose unacceptable risks to human health and the environment under current and planned future conditions. Cleanup plan requirements are established by Section 304(j) and (l)(3) of the Act and 25 Pa. Code § 250.410. Guidance on the cleanup plan is provided in Section II.B.3(g)(ii) of this manual.

☐ Submit the cleanup plan, if required, and a fee of $250.

☐ Remediate the site to the site-specific standard in accordance with the approved cleanup plan. A remedy is not required if no present or future exposure pathways exist.

☐ Establish attainment of the site-specific standard in accordance with the requirements in Chapter 250, Subchapter G, of the regulations. Guidance is provided in Sections II.B.3(g) and III.B of this manual.

☐ Calculate the mass of contaminants remediated using the procedure in Section III.C of this manual.

☐ Complete the Final Report Summary and submit electronically as instructed on the LRP web page.

☐ Submit final report, along with the optional completeness list (if used), and a fee of $500 to the Department. Include information in 25 Pa. Code §§ 250.411 and 250.204(f)(1)-(5). Include postremediation care plan in accordance with § 250.204(g) as appropriate. Document cooperation of third parties where access is needed for remediation or monitoring. Reporting requirements for the final report are described in Section II.B.3(g) of this manual.

☐ Upon the Department's approval of the final report demonstrating compliance with substantive and procedural requirements of the site-specific standard, the site is automatically afforded the liability protection as outlined in Chapter 5 of Act 2.

☐ If engineering controls are used and postremediation care is needed to maintain the standard; if fate and transport analysis indicates the standard may be exceeded at the POC in the future; if remediation relies on natural

attenuation; or if mitigation measures are implemented in accordance with 25 Pa. Code § 250.311(f), continue with the postremediation care program detailed in the final report. If areas of the source property were shown to have no current or future complete exposure pathway, the postremediation controls described in Section III.D are needed.

☐ Submit an environmental covenant, if applicable, to the Department.

☐ When the site-specific standard can be maintained without engineering controls operating and mitigation measures have been successfully sustained, document this to the Department and receive approval to end the postremediation care program.

c) Site Investigation

The principal objectives of an investigation under the site-specific standard are to characterize the nature, extent, direction, volume and composition of regulated substances that have been released and to obtain detailed site information, including identification of exposure pathways, in order to develop a protective cleanup standard unique to that site.

Important tasks during the site investigation include site characterization and pathway identification. The development of a conceptual site model and identification of contaminants of concern are also important steps in the site investigation process. This section provides specific information and procedures regarding site characterization and pathway identification. At the conclusion of the site investigation, a remedial investigation report should be submitted to the Department for review and approval (35 P.S. § 6026.304(l)(1)). Section II.A.4 of this manual describes specific information required to be included in the remedial investigation report.

i) Site Characterization

The site characterization should be conducted in accordance with scientifically recognized principles, standards, and procedures. The level of detail in the investigation needs to sufficiently characterize the nature, extent, and composition of the regulated substances that have been released. The determination of the site conditions will be used to select the remedy used to clean up the site. All interpretations of geologic and hydrogeologic data should be prepared by a professional geologist licensed in Pennsylvania.

Methodologies presented in Section II.A.4 of this manual should be followed while conducting the site investigation. When evaluating the nonpoint source groundwater discharge to surface water, a person may consult EPA guidances in "A Review of Methods for Assessing Nonpoint Source Contaminated Ground-Water Discharge to Surface Water, EPA 570/9-91-010, April 1991," and "Handbook: Stream Sampling for Waste Load Allocation Applications. EPA/625/6-86/013." Section III.A.3 of

this manual provides guidance to evaluate impacts on surface water from diffuse flow of contaminated groundwater.

As directed from specific knowledge of the subject property, including historic use or chemical usage information, and based upon the guidance in Section II.A.4 of this manual, an appropriate number of sample locations should be investigated. These sample locations should be from the identified media of concern in order to characterize the nature and composition of the contaminants, including the characterization of the source of the regulated substances. This will allow for development of a conceptual site model taking into account the vertical and horizontal extent of contamination; the direction, rate, extent and fate of contaminant movement within each medium of concern; and to identify the appropriate remedial technology options for each medium of concern.

When determining the relative location of soil or groundwater samples necessary to characterize the horizontal and vertical extent of contamination, factors such as hydraulic conductivity of the soils, heterogeneity of the soils, and the nature of the contaminants should be considered.

If groundwater is determined to be a medium of concern, adequate characterization of the effects of a release on groundwater will require a hydrogeologic study (as summarized in 25 Pa. Code § 250.204), which should include the study of the geological nature and physical properties of the underlying formation and aquifer. This study will determine how naturally occurring physical and geochemical characteristics define the hydrostratigraphy (position of aquifers, aquitards, and aquicludes) of the site, which includes an assessment of the homogeneity and isotropy of aquifer materials based on hydraulic conductivity values (measured or published), and local and regional groundwater flow directions as well as any influence from pumping centers.

Characterizing the horizontal extent of contamination of regulated substance(s) will be defined by a minimum of two rounds of groundwater sampling from properly constructed and developed monitoring wells. In some instances, additional rounds of quarterly sampling may be needed to evaluate seasonal impacts on groundwater contamination and to validate fate and transport assumptions. Please refer to Appendix A, Groundwater Monitoring Guidance, for additional information on construction and development of wells. The initial sampling event should be conducted no less than 14 days from the date of the most recent well development. A shorter time frame is permissible if it is demonstrated that, through development, pH and conductivity of the groundwater has stabilized. The second and subsequent sampling events should ideally occur sixty to ninety days from the preceding sampling event. Site-specific considerations may require adjustments to the time frame. Decisions regarding the duration of groundwater sampling should be made by

communicating with your DEP Project Officer prior to establishing a sampling plan.

When characterizing the vertical extent of groundwater contamination, consider the specific gravity of the regulated substances identified and the potential for naturally occurring or induced downward vertical hydraulic gradients. If characterizing the vertical extent of groundwater contamination is necessary, properly constructed monitoring wells or nested monitoring wells should be utilized to focus groundwater sampling in zones of potential contaminant accumulation (i.e., directly above a confining layer).

The determination of the use of groundwater is also an important task of site characterization. The uses of groundwater may include drinking water use, agricultural use, industrial uses, etc. As mandated by Act 2, groundwater will not be considered a current or potential source of drinking water where groundwater has a background TDS concentration greater than 2,500 milligrams per liter. Other than that mandate, current and future uses of groundwater must be determined on a site-specific basis. Current drinking water or agricultural uses of groundwater, at the time contamination was discovered, should be identified for protection. Additional requirements on the determination of the use of groundwater are in 25 Pa. Code § 250.403.

Development of a conceptual site model is an important step in identifying additional data needs and defining exposure. A conceptual site model identifies all potential or suspected sources of contamination, types and concentrations of contaminants detected at the site, potentially contaminated media, potential exposure pathways, and receptors. Many components of exposure (such as the source, receptors, migration pathways, and routes of exposure) are determined on a site-specific basis. The conceptual site model provides a systematic way to identify and summarize this information to ensure that potential exposures at the site are accounted for accurately.

The conceptual site model may be graphical, tabular or narrative but should provide an accurate understanding of all exposure pathways (complete and incomplete) for the site. Examples of conceptual site models may be found in EPA or ASTM guidance documents, including Section 4.2 of U.S. EPA Risk Assessment Guidance for Superfund, Volume I, Human Health Evaluation Manual (RAGS/HHEM), Part A, ASTM E-1739 RBCA, Tier 2 Guidance Manual, and ASTM E1689-95, Standard Guide for Developing Conceptual Site Models for Contaminated Sites. It is suggested that the development of the conceptual site model be coordinated with the regional project officer to ensure that potential pathways are adequately and appropriately addressed prior to performing the assessment.

ii) Pathway Identification (§ 250.404 of the Regulations)

Once the development of the conceptual site model is completed, current and future exposure pathways should be identified based on this conceptual site model. An exposure pathway describes the course a chemical or physical agent takes from the source to the exposed receptor. An exposure pathway analysis links the sources, locations, and types of environmental releases with population locations and activity patterns to determine the significant pathways of exposure.

A potentially complete exposure pathway generally consists of four elements:

- a source and mechanism of chemical release,
- a retention or transport medium (or media in cases involving media transfer of chemicals),
- a point of potential receptor contact with the contaminated medium (the exposure point), and
- an exposure route (e.g., ingestion) at the exposure point.

The person should consult the most recent U.S EPA or ASTM guidances to identify any potential current and future exposure pathways for both human and environmental receptors. The pathway identification should consider current pathways and the effects of engineering and institutional controls. Future exposure pathways should be based on currently planned and/or probable future land use. Guidance on land use considerations can be found in the USEPA Office of Solid Waste and Emergency Response (OSWER) Directive: *Land Use in The CERCLA Remedy Selection Process*. DEP guidance entitled *Site-Specific Human Health Risk Assessment Procedures* in Section III.G of this manual provides more information on pathway identification for human exposure. Guidance such as described in Sections 6.2 and 6.3 (relating to characterization of exposure setting and relating to identification of exposure pathways) of *U.S. EPA's Risk Assessment Guidance for Superfund, Volume I, Human Health Evaluation Manual* (RAGS/HHEM), *Part A*, provides a framework for pathway identification for human exposure. Subsection 6.3.2 of Risk Assessment Guidance for Superfund/Human Health Evaluation Manual (RAGS/HHEM), Part A in particular, provides guidance to perform fate and transport analysis.

Prior to the identification of exposure routes, a remediator must identify sources and receiving media, evaluate fate and transport in release media, and identify exposure points and potential receptors. The following exposure scenarios contain examples of what should be considered:

(a) Groundwater

The remediator shall identify routes of exposure for groundwater such as human exposure to groundwater by ingestion, inhalation, or dermal exposure routes. The remediator should consider effects of discharge of groundwater into surface water and the effects on ecological receptors. When evaluating the indoor exposure pathways, a remediator needs to address impacts of volatile organic compounds (VOCs) from soil and groundwater, not extraneous sources.

With respect to the groundwater ingestion pathway, the following guidance is provided. When determining whether groundwater on or off the source property must be protected under the site-specific standard for drinking water uses, the following will be applied (from 35 P.S. § 6026.304(d)):

- The ***current and probable*** future use of groundwater shall be identified and protected. Groundwater that has a background TDS content greater than 2,500 milligrams per liter or is not capable of transmitting water in usable quantities shall not be considered a current or potential source of drinking water.

- Site-specific sources of contaminants and potential receptors shall be identified.

- Natural environmental conditions affecting the fate and transport of contaminants, such as natural attenuation, shall be determined by appropriate scientific methods.

From 25 Pa. Code § 250.403 of the regulations, the following apply:

- Except for groundwater excluded by the TDS limitation described above, current and probable future use of groundwater ***shall be determined on a site-specific basis***.

- Drinking water use of groundwater shall be made suitable by at least meeting the primary and secondary MCLs at all points of exposure identified in § 250.404 (relating to pathway identification and elimination) of the regulations.

- Current drinking water or agricultural uses of groundwater, ***at the time contamination was discovered***, shall be protected.

As an example: within a city with an established public water system and groundwater contamination extending off-property, the

complete exposure pathways depend on volatilization potential of contamination and the current use or "probability" that future groundwater ingestion may occur. If surrounding properties are currently developed and have public water service, then it may be assumed that the probability is that those established patterns of water use will continue into the future. Therefore, there are no current or probable future uses of groundwater as a drinking water source; and the groundwater ingestion pathway may (all other information supporting) be determined to be incomplete.

Note that even in cases where the groundwater ingestion pathway is determined to be incomplete, the final report must include one or a combination of institutional controls or postremedial measures which provide assurance that this status continues to exist in the future. See Section III.E.3 of this manual for the range of institutional controls or postremedial measures available to a remediator. If a complete groundwater ingestion pathway is found to exist in the future, then the responsible person must demonstrate attainment of one of the three Act 2 standards.

(b) Soil

The person shall consider current and probable future exposure scenarios, such as human ingestion, dermal contact, inhalation of volatiles and particulates, and leaching to groundwater. When evaluating the indoor exposure pathways, a person needs to address impacts of VOCs from soil and groundwater, not extraneous sources.

(c) Cases Where No Complete Current or Future Exposure Pathway Exists

If no current or probable future complete exposure pathways exist without remediation, then a risk assessment report (RA), cleanup plan (CP), or attainment sampling is not required (see Figure II-17). These cases are distinct from using pathway elimination, which requires a remedy (such as an engineering and/or an institutional control) to attain the standard (see Section II.B.3(c)(ii)(d) below).

A complete exposure pathway is one in which a receptor may be exposed to contamination at any level, even if that concentration equates to an acceptable risk. If the contaminant of concern is a VOC and occupied buildings are present, then the vapor intrusion pathway must be evaluated for buildings within the applicable proximity distances and for preferential pathways (Section IV of this manual). The inhalation pathway would be complete even if vapor intrusion screening values were satisfied.

If no complete exposure pathways exist, then no remedy is required, and a risk assessment is unnecessary. Attainment sampling is also not required because there is no specific numeric concentration value (standard) applied to the site. To demonstrate attainment of the site-specific standard, a pathway elimination analysis described in 25 Pa. Code § 250.702(b)(3)(i) needs to be included in the final report. When no complete current or future exposure pathways exist, it is recommended that the remedial investigation report and the final report be combined following the suggested outline provided in Table II-7.

For groundwater, a discussion of the fate and transport analyses used during site characterization to evaluate contaminant trends for plume stability needs to be provided in the final report as required by 25 Pa. Code § 250.702(b)(2). This discussion should confirm the finding of the fate and transport analysis that the absence of complete exposure pathways will remain and that continued future attainment of the site-specific standard will be maintained. A postremediation care plan may be necessary to ensure all pathways remain incomplete and to therefore maintain attainment of the site-specific standard. The postremediation care plan, if necessary, should be submitted with the final report.

(d) Cases Where Institutional or Engineering Controls Are Needed to Eliminate Pathways

Neither a risk assessment report nor attainment sampling is required if an institutional or engineering control is used as a remedy to eliminate all complete exposure pathways. However, a cleanup plan describing how the engineering or institutional control will eliminate all complete exposure pathways is required (see Figure II-17). A suggested outline for a cleanup plan is provided in Table II-5. The cleanup plan, the remedial investigation report, and the final report can be submitted simultaneously. Fate and transport analysis descriptions and final report requirements as described in Section II.B.3(c)(ii)(c) also apply in this scenario. Note that if one part of a combined report is disapproved, then all other parts of the combined report that depend on the disapproved part will also require re-submittal, with new notices and payment of fees. For example, if a cleanup plan is disapproved, then the cleanup plan and final report must be re-submitted. However, if one part of a combined report is deficient, the remediator may have a chance to correct the deficiency in a prescribed timeframe to avoid re-submittal of notices and payment of fees.

d) Risk Assessment and Development of Site-Specific Standards (§ 250.402)

This section provides general information on risk assessment, developing site-specific standards, and pathway elimination. Sections III.G and H of this manual provide guidance on site-specific human health and ecological risk assessment procedures. This guidance should be followed to conduct a baseline risk assessment or to develop site-specific standards.

Any remediator selecting the site-specific standard established by Section 304 of Act 2 should submit a risk assessment report to the Department for review and approval unless no present or future complete exposure pathways exist as demonstrated by a fate and transport analysis when the site was characterized. If no such complete exposure pathways exist, a person only needs to submit a combined remedial investigation report and final report (see Table II-7). If complete exposure pathways exist, the fate and transport analysis, which is a part of the exposure assessment performed during site characterization, should be documented in the exposure assessment section of the risk assessment report.

Although it might be helpful in some cases to establish the leaching potential of constituents in soil, meeting toxicity characteristic leaching procedure (TCLP) limits does not automatically indicate attainment of the site-specific standard. TCLP analysis is used for Resource Conservation and Recovery Act (RCRA) hazardous waste determinations to simulate leaching in a landfill. These results determine if a waste is hazardous and can or cannot be disposed of in a landfill. TCLP analysis does not provide useful data for calculation of site-specific risk values. The risk associated with the regulated substances is considered in the site-specific risk assessment under Act 2.

To determine if a site-specific risk assessment is necessary, a conceptual site model should be developed that defines potential exposure scenarios and pathways. The exposure scenario (e.g., residential, industrial, recreational), which will define the exposure pathways, must be based on site-specific land use considerations. The pathways, which describe the mechanism by which receptors may be exposed to a source, are also site-specific. Engineering or institutional controls that are to be implemented which will eliminate exposure pathways must be incorporated into the conceptual site model. Then, a risk assessment only needs to be performed if complete exposure pathways for humans and/or ecological receptors exist under current or future planned conditions.

A complete exposure pathway exists if there is a receptor to be exposed through an exposure route. For ecological receptors, a pathway is complete even if the current ecological receptors are not present as a result of the contamination. A pathway is not complete if there is no reasonable exposure route; i.e., the contaminant is not in an available form to affect the receptors.

However, before getting into the mechanics of performing the risk assessment, it is important to clearly define the problem that is to be addressed, the objectives of the study, and how the results will be used to meet these objectives. This initial step is critical to ensure a successful outcome (accurate, protective, timely, cost-

effective evaluation) and that the level of effort is commensurate with the scope of the problem.

Under Act 2, a risk assessment report may include the following:

- A baseline risk assessment report that describes the potential adverse effects to both human and ecological receptors, under both current and planned and/or probable future conditions that are caused by the presence of regulated substances in the absence of any further control, remediation, or mitigation measures.

- A risk assessment report that documents which exposure pathways will be eliminated by a pathway elimination measure so that any substantial present or probable future risk to human health or the environment is eliminated.

- A risk assessment report that describes the methods used to develop a concentration level at which human health and the environment are protected.

- The comments obtained as a result of a public comment period, if any, and the responses to those public comments.

If an unacceptable risk is identified at a site, a person may develop site-specific standards based on a site-specific risk assessment. A baseline risk assessment report is not required if the Department, in its remedial investigation report or cleanup plan approval, determines that a specific remediation measure, other than a no-action remedial alternative, can be implemented to attain the site-specific standard (see 35 P.S. § 6026.304; 25 Pa. Code § 250.405(c)). A baseline risk assessment is that portion of a risk assessment that evaluates a risk in the absence of the proposed site-specific measure.

In developing site-specific standards, a person may use the toxicological data presented in Tables 5a and 5b of Appendix A, Chapter 250, refer to the toxicity database on the Land Recycling website, or refer to the sources listed in 25 Pa. Code § 250.605 for the most up-to-date values.

As an alternative to developing site-specific numerical cleanup standards and remediation, individuals may choose to perform a combination of engineering and institutional controls to achieve pathway elimination for regulated substances of concern. Common methodologies used to eliminate exposure pathways include permanent capping of contaminated soils with parking lots or building slab construction, groundwater and land use restrictions, vapor barriers, or sub-slab depressurization systems.

Remediation measures may require interface with the SWMA (see Section V.A of this manual), particularly for offsite removal of contaminated media or management of existing waste onsite.

To prepare the development of the site-specific standards risk assessment report, all current and probable future complete exposure pathways as identified in the fate and transport analysis should be addressed. When pathway elimination measures are planned and preapproved, the remaining pathways and the eliminated pathways under the postremedial conditions should be identified in the site-specific standard risk assessment report. Site-specific cleanup levels should be developed to address the risks associated with these remaining pathways. Where all pathways have not been eliminated, a risk assessment report is required.

In addition to human health protection, the risk assessment must evaluate ecological receptors. An ecological risk assessment should be conducted with considerations of the site-specific ecological risk assessment procedure provided in Section III.H of this manual and the most recent U.S. EPA or ASTM guidances, including those listed in Table II-4 to determine whether an impact has occurred or will occur if a release goes unabated, to establish acceptable remediation levels or alternative remedies based on current or probable future land use that are protective of the ecological receptors.

Ecological receptors include:

- Individuals of threatened or endangered species as designated by the U.S. Fish and Wildlife Service under the Endangered Species Act.

- Exceptional value wetlands as defined in 25 Pa. Code § 105.17 (relating to wetlands).

- Habitats of concern as defined in 25 Pa. Code § 250.1.

- Species of concern as identified in the PNDI.

At the conclusion of the risk assessment, a risk assessment report should be submitted to the Department for review and approval. Section II.B.3(g) (v) of this manual describes specific information required to be included in the risk assessment report.

To ensure that any substantial present or probable future risk to the environment is eliminated, both human health and ecological risk evaluations are necessary. The objective of the Preliminary Ecological Screening is to quickly evaluate whether surface soil or sediments at a site have the potential to pose significant ecological impact or impacts requiring further evaluation. The site-specific initial screening procedure described in Section III.H of this manual may be used during or immediately after the site characterization process to assess the potential for significant ecological impact. It should be noted that the ecological screening procedures under the SHS (in Section II.B.2(e) of this manual) should not be used to replace the site-specific initial screen procedure (Steps 1-2 in Section III.H of this manual) when the site-specific standard is selected to protect human health and the environment. This is because the assumption to use the ecological screening procedures under the SHS is that the site has met SHS values to protect

human health. This underlying assumption cannot be made when the site-specific standard is selected to protect human health.

- When conducting an ecological screening under the site-specific standard, a screening level ecological risk assessment to determine if an impact has occurred or will occur if the release of a regulated substance goes unabated should be performed. If this risk assessment shows that an impact has or will occur, the following are then necessary: an ecological risk assessment conducted in accordance with Department-approved EPA or ASTM guidance to establish acceptable remediation levels or alternative remedies based on current and future use that are protective of ecological receptors.

Table II-3: List of Ecological Risk Assessment Guidances

U.S. EPA. 1997. Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments. EPA/540-R-97-006. PB97-963211. June 16, 1997.

U.S. EPA. 1993b. Wildlife Exposure Factors Handbook, Volume II of II, Appendix: Literature Review Database. EPA/600/R-93/187b. PB94-177789. December, 1993.

U.S. EPA. 1992. Guidelines for Exposure Assessment; 57 FR, 22888-22938, May 29, 1992

ASTM, E 1739, Standard Guide for Risk-Based Corrective Action Applied at Petroleum Release Sites.

Refer to the EPA website for the Region 3 BTAG (Biological Technical Assistance Group) screening tables and the SSL (Soil Screening Levels) tables as well as the National Oceanic and Atmospheric Administration (NOAA) website for the SQuiRT (Screening Quick Reference Tables) ecological screening values.

- Implementation of the selected remedy, which may include mitigation measures under § 250.311(f), that is protective of ecological receptors.

e) Cleanup Plan

Section II.B.3.g.ii and Table II-5 of this manual describe information required to be included in the cleanup plan. A cleanup plan is not required, and no remedy is required to be proposed or completed if neither current nor future exposure pathways exist. Subject to the Department's approval of the baseline risk assessment report, a cleanup plan is also not required if the baseline risk assessment indicates the site is within the human health and environmental protection goals specified in 25 Pa. Code § 250.402 under both current and currently planned future site conditions. After the site has been characterized using the suggested guidelines (or some equivalent technique) and a risk assessment performed to develop site-specific standards for soil and groundwater, a remediation (cleanup) plan should be developed, which consists of identification and evaluation of remedial alternatives, selection of a proposed remedy, and plans for the development, construction, and initial operation of the proposed remedy. A number of factors required by Act 2 for consideration in selecting the remedy are set forth in Section 304(j) of Act 2. As described in Section 304(i) of Act 2, remediation to site-specific standards may include treatment, removal, engineering or institutional controls as well as innovative or other demonstrated measures. However, fences or warning signs generally may not be used as the sole means to address a complete exposure pathway.

To evaluate the short-term and long-term effectiveness of a remedial alternative, the potential risk associated with implementation of the alternative and the risk associated with exposure to the remediated media must be evaluated. The pathways and exposure factors that were defined in the exposure assessment should be used to characterize these potential risks.

The risk characterization associated with short-term effectiveness considers the exposure of workers at the site and exposure of receptors in the vicinity surrounding the site to migrating media during the implementation of the remedial alternative. A comparison of a focused list of remedial alternatives may help predict the risks associated with the implementation of the remedial alternative or whether the implementation of alternatives may have any significant impact to human health and the environment.

The risk characterization associated with long-term effectiveness evaluates whether the remedial alternative may attain the remedial objectives (site-specific standards) and whether postremedial risks may achieve the acceptable levels of risk. At times, a specific cleanup goal for one constituent may not be attained, but the overall postremedial risk may be within acceptable levels. Evaluation of the postremedial risk is based on a prediction of what the postremedial exposure concentration would be. If bioremediation is considered, the remedial objective would be the concentration that provides the basis for characterization of the

postremedial risk. If the calculated postremedial risk is within the acceptable range, the remedial alternative would be considered a viable solution.

A remediator evaluating long-term and short-term risks of remedial alternatives should consider *EPA's Risk Assessment Guidance for Superfund* (RAGS), Volume 1, Part C, Chapter 2 for additional guidance. It should be noted that a quantitative risk assessment of remedial alternatives will not need to be conducted for all sites. In most cases, a qualitative rather than a detailed quantitative evaluation of both long-term and short-term risks is all that is needed to select the most appropriate alternative. However, the Department may require a quantitative risk assessment of the selected remedy if a quantitative risk assessment is needed to select the most appropriate remedy or a perceived risk of a selected remedy is high. No matter whether the risk evaluation is qualitative or quantitative, the cleanup plan should always discuss the degree of uncertainty associated with the risk assessment of the selected remedy.

Where there are imminent or immediate threats to human health or the environment, such as waste releasing from corroding tanks or drums, mitigating measures should be undertaken to prevent releases and further exposure as soon as these threats are identified.

The cleanup plan must document the evaluation of the factors listed in Section 304(j) of Act 2. The Department will review the alternative evaluated, the evaluation of the selected remedy in terms of the Section 304(j) criteria, public comments, and response to the comments in the cleanup plan. The Section 304(j) criteria address a few general areas, such as the effectiveness of the remedy (long/short term) to manage risk; the extent to which the risks are being reduced; the ability to implement the remedy; reduction of toxicity, mobility, or volume of regulated substances; reliability and postremediation care; and cost-benefit considerations.

The Department may require further evaluation of the selected remedy or of one or more alternative remedies on its own analysis of Section 304(j) factors in Act 2 or in response to comments received from the community surrounding the site as a result of the implementation of the community involvement plan or as a result of the Department's review of the cleanup plan. Remediators shall submit to the Department, upon request, such additional information as may reasonably be required to complete the evaluation. A final report cannot be approved prior to a remedy being in place as specified in 25 Pa. Code § 250.411(b).

f) Remediation and Demonstration of Attainment

Remediation to the site-specific standards should be implemented in accordance with the approved cleanup plan.

The POC for demonstration of the attainment of site-specific standards is described in 25 Pa. Code § 250.407. Site-specific standards shall be attained at and beyond the POC, where the plume has migrated beyond the property boundary. For groundwater, the POC is the property boundary that existed at the

time the contamination was discovered. The remediator may request the movement of the POC in certain circumstances described in 25 Pa. Code § 250.407(a). If any of those conditions exist, the remediator must request moving the POC in writing prior to or at the time of submission of the cleanup plan. The Department will provide a written response to the request. The Department's written approval must be obtained before using the adjusted POC.

Unless an NPDES permit is required for purposes of complying with surface water quality in a spring, the POC is the point of first designated or existing use as defined in 25 Pa. Code §§ 93.1, 93.4, and 93.9. This could mean in close proximity to the spring itself or some point downstream from the spring discharge. Determining the point of first designated use is required because it establishes the point where Chapter 93 water quality standards apply.

Technical guidance to determine point of first use is found in *Policy and Procedure for Evaluating Wastewater Discharges to Intermittent and Ephemeral Streams, Drainage Channels and Swales, and Storm Sewers*, DEP document # 391-2000-014, revised April 2008. In essence, this guidance relies on biological techniques to determine the first downstream point where aquatic life can be documented. It applies to both perennial and intermittent streams with definable bed and banks, but not to ephemeral streams, that is, areas of overland runoff which occur only during or immediately following rainfall events and where there is no defined stream channel and stream substrate.

The site characterization will be the basis on which the vertical and horizontal extent of contamination above the standard is determined. Once this volume of the site is determined and remediation, if necessary, has been performed, then attainment of the standard will focus on the environmental media contained within that volume of the site. Where multiple releases occur on a property which produce distinctly separate zones of contamination, the characterization and subsequent attainment demonstrations will apply individually to the separate releases.

The three methods to demonstrate that the site-specific standard has been met are pathway elimination using an engineering/geologic evaluation, the 95% UCL of the arithmetic mean or other appropriate statistical methods to show that the site meets numerical site-specific standards, or a residual risk assessment following implementation of the remedy to demonstrate that the risk associated with the site following remediation falls within the allowable risk range in Act 2. The residual risk assessment will be based on resampling and a reassessment of the cumulative risks associated with concentrations occurring following remediation.

If this residual risk assessment is nothing more than a presentation of the recalculation of risk values that were previously presented in an approved risk assessment report, the presentation of these calculations can be considered as part of the final report and are not subject to the fees and notification requirements of a risk assessment. However, if the residual risk assessment is following remediation done prior to approval of a risk assessment report, or following a change in pathway and exposure factors due to remedial measures not addressed

in the prior report, this must be a full report as defined in § 250.602 of the regulations and explained further in Section III.H of this manual. This type of residual risk assessment is subject to the fees and reporting requirements associated with a risk assessment.

In demonstrating attainment of the site-specific standard, concentrations of regulated substances are not required to be less than the limit related to the PQL for that substance as provided for in 25 Pa. Code § 250.701(c) and as described in Section III.F of this manual.

In demonstrating attainment of the site-specific standard, the removal of SPL is not required if attainment can be demonstrated in accordance with the requirements of 25 Pa. Code § 250.702(b)(3).

If the site-specific standard is numerically less than the background standard, the remediator may select the background standard, and attainment of the background standard should be demonstrated according to Section 303 of Act 2.

To ensure that contaminant concentration at the POC will not exceed the selected standard in the future, a statistical time trend analysis, knowledge of the plume stability, or other acceptable method must be provided in the final report to the Department for review and approval.

Guidance on applying statistical methods to demonstrate attainment can be found in Section III.B of this manual. A remediator should consider the general guidelines of risk assessment in Sections III.H and III.I of this manual to perform the residual risk assessment. When submitting the final report, a remediator should ensure that the items identified in Section II.B.3(g) and Table II-6 of this manual are included.

g) General Report Guidelines for the Site-Specific Standard

The remedial investigation report, risk assessment report, cleanup plan, and final report detailed below are not to be submitted to the Department until the 30-day public and municipal comment period has expired.

i) Remedial Investigation Report (25 Pa. Code § 250.408)

The site characterization shall be conducted in accordance with scientifically recognized principles, standards and procedures. The level of detail in the investigation and the selected methods and analyses, which may include models, shall sufficiently define the rate of movement and the present and future extent and fate of contaminants to ensure continued attainment of the remediation standard. All interpretations of geologic and hydrogeologic data shall be prepared by a professional geologist licensed in Pennsylvania. A suggested outline for a remedial investigation report is provided in Table II-4.

ii) Cleanup Plan (25 Pa. Code § 250.410)

The cleanup plan is not required if no current and probable future exposure pathways exist. The cleanup plan is also not required if the approved baseline risk assessment report indicates that the site does not pose unacceptable risks to human health and the environment under current and planned or probable future conditions. A suggested outline for a cleanup plan is provided in Table II-5.

iii) Final Report (25 Pa. Code § 250.411)

A suggested outline for a final report under the site-specific standard is provided in Table II-6.

iv) Combined Remedial Investigation Report/Final Report

The site characterization shall be conducted in accordance with scientifically recognized principles, standards and procedures. The level of detail in the investigation and the selected methods and analyses, that may include models, shall sufficiently define the rate of movement and the present and future extent and fate of contaminants to ensure continued attainment of the remediation standard. All interpretations of geologic and hydrogeologic data shall be prepared by a professional geologist licensed in Pennsylvania. A suggested outline for the combined remedial investigation report/final report under the site-specific standard is provided in Table II-7.

v) Risk Assessment Report (25 Pa. Code § 250.409)

A baseline risk assessment report is not required if the Department, in its remedial investigation report or cleanup plan approval, concurs that a specific remediation measure that eliminates all pathways, other than a no-action remedial alternative, can be implemented to attain the site-specific standard (see 25 Pa. Code § 250.405(c)). A risk assessment report is not required if no present or future exposure pathways exist, as documented in the remedial investigation report by a fate and transport analysis.

A suggested outline for a risk assessment report is provided in Table II-8. The items in the outline are suggested as minimum requirements for inclusion in the report; the order and titles are not mandatory. If a baseline risk assessment is not required and a remediator submits the development of site-specific standard numerical values as a stand-alone document, more detailed risk assessment information should be provided in the development of the site-specific standard numerical values document.

h) Detailed Report Requirements for the Site-Specific Standard

The following are detailed descriptions of what should to be included in each section of a report. Not all sections are necessary for each report. Please refer to the outlines in the previous section for detailed information.

i) Summary (RIR, FR, RIR/FR)

Provide a summary paragraph(s) which will provide the reviewer with an overview of the site. This will serve to highlight the important issues and conclusion which will be presented in the report.

The Final Report Summary form should be filled in and submitted to the Department electronically. The summary submitted with the final report should be a copy of that electronic form.

ii) Introduction (CP, RA)

Provide a summary of the investigation report(s) and risk assessment report and an interpretation of the conditions at the site (refined conceptual site model). Discuss the chosen method(s) of remediation. The remedy should be evaluated in accordance with the requirements of Section 304(j) of Act 2.

iii) Site Description (RIR, RIR/FR)

Provide a description of the site in sufficient detail to inform the reviewer of the site location and the types of operations that are currently and/or were formerly conducted on the site. As appropriate to the site, the description should include location, physical description of the property, ownership history, site use history, and regulatory action history (past cleanups).

iv) Site Characterization (RIR, RIR/FR, RA)

The site characterization provides important information documenting the current conditions at the site. Information developed during the site characterization is primarily intended to describe the nature, concentrations, extent, and potential for movement of all contaminants present on the site or that may have migrated from the site. For sites where there are multiple distinct areas of contamination, the site characterization process should be applied to each area individually.

v) Source and Identification of Constituents of Concern (Part of Characterization)

For the area being investigated include a description of source characterization, which may be in the form of a conceptual site model.

vi) Nature and Extent of Contamination (Part of Characterization)

Information needed to meet the requirements below should be included here. For soil and groundwater, include information on samples and measurements used to characterize the horizontal and vertical, present and future extent and fate of contamination. Direction and velocity of contaminant movement should be based on factors of the groundwater and soil as well as the contaminant(s) which affect migration.

Text, tables, graphics, figures, maps and cross sections should be used to describe the nature, location, and composition of the regulated substances at the site. Providing the data in an appropriate format will expedite the review of the report.

vii) Other Information Required Under the Site-Specific Standard (RIR, RIR/FR)

Description of the existing or potential public benefits of the use or reuse of the property for employment opportunities, housing, open space, recreation or other uses. Describe the past, present, and future use of the site.

Information obtained from attempts to comply with the background or Statewide health standards, such as background concentrations for constituents of concern.

viii) List of Contacts (ALL)

Name, address, and telephone number of the project manager responsible for submittal of the cleanup plan.

Names, addresses, and telephone numbers of consultants or other persons responsible for preparing the cleanup plan.

Names, addresses, and telephone numbers of the property owner and party responsible for the remediation cost.

ix) Remedial Alternative (CP)

Identify remediation alternatives considered and evaluate the ability and effectiveness of the selected remedy to achieve the site-specific standards, based on the factors set forth in Section 304(j) of Act 2. The cleanup plan must document how each of the factors set forth in Section 304 (j) of Act 2 was evaluated. The evaluation should include an evaluation of the short-term and long-term risks and effectiveness of the proposed remedy. In evaluating the other alternatives, no risk evaluation is required; rather, a narrative describing the consideration of Section 304(j) factors relative to the proposed remedy should be included.

x) Treatability studies (CP)

Provide results of any treatability, bench scale, or pilot scale studies or other data collected to support the remedial action(s).

All other site information relevant to the conceptual design, construction, or operation of the remedial action.

Specific characteristics of the site that may affect the implementation or effectiveness of the remedial action including such characteristics as topography, geology, depth of bedrock, potentiometric surfaces, and the existence of utilities.

xi) Design plans and Specifications (CP)

Consists of adequate design plans and specifications sufficient to evaluate the proposed remedy including, but not limited to:

- Detailed description of the remedial action (treatment and/or removal) and remedial technology to be implemented. Adequate design plans and specifications for all remedial activities, including remedial design, onsite treatment, storage, removal and disposal activities.

- Estimated volume of each medium to be treated and/or removed. Provide methodology and calculations used to estimate contaminant mass.

- Remedial Action Status Plan - To evaluate the short-term and long-term effectiveness of the remedial action to include, but not limited to, the following:

  – Location and construction details of all monitoring points.

  – Sampling and Analysis Plan, including QA/QC Plan.

  – Other site-specific monitoring as appropriate.

- Construction QA/QC Plan including engineering certification.

- Locations, telephone numbers, and contacts of offsite disposal facilities, including names, addresses, and telephone numbers of waste transportation companies.

- Site-specific Health & Safety Plan which includes adherence to all applicable Occupational Safety and Health Administration (OSHA) and National Institute for Occupational Safety and Health (NIOSH) regulations and recommendation.

- Erosion and Sedimentation Control Plan consistent with Chapter 102 (Erosion Control) relating to earth disturbance during remedial activities.

- Site Security Plan.

- A schedule for implementation of the proposed remedial action.

- Operation and Maintenance Plan which shall describe:

  – Startup testing, inspection and maintenance over the first year and subsequent years of operation.

  – Identification of equipment necessary for operation and maintenance.

  – Specification of the type, frequency, and duration of testing or maintenance to verify optimal remedial system performance.

- All federal, State and local permits and approvals and any agreements necessary for the construction and operation of the approved remedial action shall be identified.

xii) Remediation (FR)

Documentation of the methodologies used to attain the site-specific standard. Including removal and/or treatment technologies used, and any engineering and/or institutional controls used to attain or maintain the selected standard. This section should also include the calculation of the mass of contaminants addressed during the remediation of soil and/or groundwater, using the methodology in Section III.C.

xiii) Attainment (FR)

Documentation that the remedy has been completed in accordance with an approved cleanup plan.

- Descriptions of treatment, removal, or decontamination procedures performed in remediation. Documentation of handling of remediation wastes in accordance with applicable regulations.

- Descriptions of the sampling methodology and analytical results.

- All sampling data, including QA/QC data.

The demonstration of attainment should be applied separately for each distinct area of contamination. Demonstration of attainment in a final

report should include one or more of the following three types of information:

- Demonstration of attainment of a numerical standard:

  The information includes demonstration that the calculated numerical site-specific standards have been met through the application of appropriate statistical tests, and demonstration that shows contaminant concentration at the POC will not exceed the selected standard. The following information shall be documented in a final report when a statistical method is applied:

  – A description of the statistical method.

  – A clear statement of the applicable decision rule in the form of statistical hypothesis for each spatial unit and temporal boundary including the applicable statistical parameter of interest and the cleanup standard.

  – A description of the underlying assumptions of the method.

  – Documentation showing that the sample data set meets the underlying assumptions of the method and demonstrate that the method is appropriate to apply to the data.

  – Specification of false positive rates.

  – Documentation of input and output data for the statistical test, presented in tables, figures or both, as appropriate.

  – An interpretation and conclusion of the statistical test.

  Demonstration that contaminant concentration at the POC will not exceed the selected standard should be based on a statistical time trend analysis, knowledge of the plume stability or other acceptable method.

- Demonstration of pathway elimination:

  This demonstration should be based on either an engineering or hydrogeologic analysis, or both, which includes fate and transport analysis that some or all of the exposure pathways have been eliminated. The eliminated pathways and the remaining pathways should be clearly identified. The pathway elimination demonstration should include the following:

- Identifying all exposure pathways prior to the implementation of pathway elimination technology, based on fate and transport analysis.

- Identifying all exposure pathways after the implementation of pathway elimination technology, based on fate and transport analysis.

- Residual Risk Assessment

  As an alternative to demonstrating the attainment of numerical standards, a person may perform a residual risk assessment to show that the risk which remains at a site following remediation is within the acceptable risk range specified in Act 2. The residual risk assessment should be based on resampling and a reassessment of the cumulative risks associated with concentrations occurring following remediation.

  If this residual risk assessment is nothing more than a presentation of the recalculation of risk values that were previously presented in an approved risk assessment report, the presentation of these calculations can be considered as part of the final report and are not subject to the fees and notification requirements of a risk assessment. However, if the residual risk assessment is following remediation done prior to approval of a risk assessment report, or following a change in pathway and exposure factors due to remedial measures not addressed in the prior report, this must be a full report as defined in 25 Pa. Code § 250.602 and explained further in Section III.H of this manual. This type of residual risk assessment is subject to the fees and reporting requirements associated with a risk assessment.

xiv) Fate and Transport Analysis (RIR, FR, RIR/FR, RA)

The Fate and Transport Section (Section III.A of this manual) provides a discussion on fate and transport analysis. The amount of detail in the fate and transport analysis may vary from a basic description to a very extensive detailed model with quantitative modeling. Whenever a model is used, the assumptions, data, and information on the model necessary for Department staff to evaluate and run the model should be included. Any parameters used in the analysis or models used should use data from the site obtained during the site characterization. This includes identified ecological receptors.

Modeling (optional) - Data Interpretation:

- Identify any programs or modeling used to interpret site conditions or predict plume migration. Identify codes used and any modifications made.

- Models should be developed from site-specific data.
- Identify limitations/assumptions used in the model(s).
- Models should be validated to reproduce conditions measured in the field.

xv) Conclusions and Recommendations (RIR, RIR/FR)

In addition to documenting the items listed above, the remedial investigation report should draw conclusions regarding the existence of exposure pathways and the potential effectiveness of institutional or engineering controls in eliminating some or all of these pathways. The report also should identify the appropriate remedial technology options for each medium of concern.

xvi) Postremediation care plan (if applicable) and other postremedial obligations (such as monitoring or institutional controls) (CP, FR, RIR/FR)

If engineering or institutional controls are needed to maintain a standard, if the fate and transport analysis indicates that the remediation standard may be exceeded at the POC in the future, or, if the remediation relies on natural attenuation, a postremediation care plan must be documented in the final report (see 25 Pa. Code 250.411(d)). The plan should include:

- Reporting of any instance of nonattainment.
- Reporting of any measures to correct nonattainment conditions.
- Monitoring on a quarterly basis, or as otherwise approved by the Department, that demonstrates the effectiveness of the remedy and periodic reporting of monitoring results and analysis.
- Maintenance of records at the property where the remediation is being conducted for monitoring, sampling and analysis.
- A schedule for operation and maintenance of the controls and submission of any proposed changes.
- If requested by the Department, documentation of financial ability to implement the remedy and the postremediation care plan.

If mitigation measures are implemented to restore or replace equivalent ecological resources in the local area of the site, a postremediation care plan to maintain the mitigated ecological resources is documented in the final report (see 25 Pa. Code 250.411(f)). The plan should include:

- Reporting of the ongoing success or failure of the mitigation measure implemented.

- Mitigation measures instituted at the time of the final report shall be successfully accomplished and sustained up to five years from final report approval.

- In some cases, postremedial obligations described in Section III.E could require documentation in a postremediation care plan.

xvii) Cooperation or Agreement of Third Party (CP)

When a person proposes a remedy that relies on access to properties owned by third parties for remediation or monitoring, documentation of cooperation or agreement shall be submitted (see 25 Pa. Code 250.410(c)).

xviii) Public comments (ALL)

Include the comments obtained during the public and municipal comment period and the public involvement plan, if any, and the responses to those public comments.

xix) References (ALL)

xx) Attachments (ALL)

Attachments may include but are not limited to:

- Tables – monitoring well construction summary, groundwater gauging data, including elevation and NAPL thicknesses, analytical data, historical data.

- Figures – including groundwater elevation maps, extent of NAPL, concentration data for soil/groundwater/surface water/vapor or indoor air, cross-sections.

- Monitoring well construction diagrams, boring logs, stratigraphic logs, including soil/rock characteristics.

- Sampling and analysis plan(s).

- QA/QC Plan.

- Ecological survey documentation (from PNDI).

- Well search documentation (from PaGIS).

- Field data sheets, such as low flow purging monitoring.

- Statistical worksheets, software outputs, graphs; modeling inputs/outputs.

- Disposal documentation of soil/groundwater.

- Remediation system operation, maintenance, monitoring data; mass removal estimates.

- Before and after remediation photographs.

- Copy of municipal notification, reasonable proof of newspaper notice publication.

- Laboratory reports and any voluminous attachments may be enclosed on a CD.

xxi) Signatures (ALL)

If any portions of the submitted report were prepared or reviewed by or under the responsible charge of a registered professional geologist or engineer, the professional geologist or engineer in charge must sign and seal the report.

Table II-4: Suggested Outline for Remedial Investigation Report under the Site-Specific Standard

I. Summary

(Section II.B.3(h)(i))

II. Site Description

Provide a description of the site in sufficient detail to give an overall view of the site. (Section II.B.3(h)(iii))

III. Site Characterization

Document current conditions at the site. (Section II.B.3(h)(iv-vi))

IV. Fate and Transport Analysis

Description of Fate and Transport analyses used and results and conclusions. Provide detailed conceptual site model including analysis of vapor intrusion pathway. (Sections II.B.3(h)(xiv) and III.A)

V. Other Information Required under the Site-Specific Standard.

Provide the results of ecological receptor evaluation. Describe the public benefits of the use or reuse of the property. Identify complete exposure pathways. (Section II.B.3(h)(vii))

VI. Conclusions and Recommendations

Draw conclusions regarding the existence of exposure pathways and the potential effectiveness of institutional or engineering controls for pathway elimination. Identify the appropriate remedial technology options. (Section II.B.3(h)(xv))

VII. References

VIII. Attachments

(Section II.B.3(h)(xx))

IX. Public Comments

Include the comments obtained as a result of a public involvement plan, if any, and the responses to those public comments. (Section II.B.3(h)(xviii))

X. Signatures

(Section II.B.3(h)(xxi))

Table II-5: Suggested Outline for a Cleanup Plan under the Site-Specific Standard

I. Introduction

(Section II.B.3(h)(ii))

II. List of Contacts

(Section II.B.3(h)(viii))

III. Site Maps

(Section II.B.3(h)(xx))

IV. Remedial Alternative

Identify remediation alternatives considered and evaluate the ability and effectiveness of the selected remedy to achieve the site-specific standards based on the factors set forth in Section 304 (j) of Act 2. (Section II.B.3(h)(ix))

V. Treatability Studies

Provide results of any treatability, bench scale, or pilot scale studies or other data collected to support the remedial action(s). (Section II.B.3(h)(x))

VI. Design Plans and Specifications

Consists of design plans and specifications sufficient to evaluate the proposed remedy. (Section II.B.3(h)(xi))

VII. Postremediation Care Plan

(Section II.B.3(h)(xvi))

VIII. Cooperation or Agreement of Third Party

(Section II.B.3(h)(xvii))

The final report summary should be a copy of the electronic form submitted to the Department. (Section II.B.3(h)(i))

II. Site Description

Provide a description of the site in sufficient detail to give an overall view of the site. (Section II.B.3(h)(iii))

III. Site Characterization

Document current conditions at the site. (Sections II.B.3(h)(iv-vi))

IV. Fate and Transport Analysis

Description of fate and transport analyses used and results and conclusions. (Sections II.B.3(h)(xiv) and III.A)

V. Other Information Required under the Site-Specific Standard

Provide the results of ecological receptor evaluation. Describe the public benefits of the use or reuse of the property. Identify complete exposure pathways. (Section II.B.3(h)(vii))

VI. Conclusions and Recommendations

Draw conclusions regarding the existence of exposure pathways and the potential effectiveness of institutional or engineering controls for pathway elimination. Identify the appropriate remedial technology options. (Section II.B.3(h)(xv))

VII. Postremediation Care Plan (if applicable)

This section is included only if necessary. It describes the engineering and institutional controls necessary to maintain the standard. (Section II.B.3(h)(xvi))

VIII. References

IX. Attachments

(Section II.B.3(h)(xx))

X. Public Comments

XI. Signatures

(Section II.B.3(h)(xxi))

Table II-8: Suggested Outline for a Risk Assessment Report under the Site-Specific Standard

EXECUTIVE SUMMARY

PART 1 – Human Health Risk Assessment

I. Introduction

- Objectives of Risk Assessment
- Organization of Report

II. Site Characterization

- Site history (brief)
- Site location/map
- Description of sources
- Nature and extent of contamination
- Identification of constituents of concern
- Conceptual site model

III. Exposure Assessment

- Exposure scenarios based on land use (current and future)
- Potential receptors based on land use (current and future)
- Summary of complete pathways (including fate and transport considerations)
- Quantification of exposure (not required, if all exposure pathways will be eliminated through pathway elimination measures.)

IV. Toxicity Assessment

(Not required if all exposure pathways will be eliminated through pathway elimination measures.)

- Toxicity values for constituents of concern
- Derivation of chemical-specific toxicity criteria (if applicable)
- Supporting data listing all relevant information on toxicity

V. Risk Characterization

- Algorithms (not required if all exposure pathways will be eliminated through pathway elimination measures.)
- Calculations and Results (not required if all exposure pathways will be eliminated through pathway elimination measures.)
- Description and fulfillment of risk assessment objectives
- Discussion of uncertainty for all sections of report, including uncertainties associated with site characterization, toxicity assessment, exposure assessment and risk characterization

VI. References

PART 2 – Ecological Risk Assessment

This section reports the results of the ecological risk assessment conducted using the guidance in Section III.I and, as applicable, EPA guidance.

Public Comments

Include the comments obtained as a result of a public involvement plan, if any, and the responses to those public comments.

Signatures

If any portions of the submitted report were prepared or reviewed by or under the responsible charge of a registered professional geologist or engineer, the professional geologist or engineer in charge should sign and seal the report.

4. Special Industrial Areas

a) Introduction

The SIA provision established in Section 305 of Act 2 creates incentives to reuse industrial properties. Cleanups at these SIAs have reduced remediation requirements which are intended to allow these sites to be put back into productive use in the community. Act 2 established this provision to encourage the redevelopment of properties used for industrial activities. The remediator, reuser, and the property must meet eligibility requirements to be considered as an SIA under Act 2. Under the SIA provision, necessary remediation will be performed, and required notification and reporting requirements will be met.

b) Eligibility Determination

Specific eligibility requirements in § 250.502 of the regulations provide for qualification of a property for reuse as an SIA and for the qualification of a remediator to use this special provision of Act 2. The property must have been used for industrial activity. The extent of industrial activity is defined very broadly and is detailed in Section 103 of Act 2. If the property qualifies as having been used for industrial activity, the following additional qualifications must be met:

- The property must be one where there is no financially viable responsible person, or it is located within a designated EZ.

- The remediator must not have caused or contributed to releases at the property. A person who is interested in purchasing a property and undertaking a reuse of that property should contact the Department before the reuser purchases the property.

- The term “responsible person” includes the owner of the property, regardless of whether he has or has not caused or contributed to the contamination. Therefore, prospective purchasers of property which could be eligible as an SIA are recommended to contact the Department prior to the purchase of the property.

- Actions in themselves that do not cause or contribute to contamination taken under Section 307 of Act 2 relating to emergency and interim responses will not prejudice eligibility determinations under the SIA designation.

- It is the responsibility of the reuser to demonstrate to the Department that the reuser has not had an environmental impact on the property, just as it is the responsibility of the remediator to document that the property meets the other eligibility criteria for an SIA. To accomplish this, certain information must be presented to the Department regarding the above eligibility requirements:

- Documentation that the property has been used for industrial activities by including information on the ownership and operational history of the property as part of the work plan for the baseline remedial investigation.

- Verification that no financially viable responsible party exists to address the contamination on the property. Financial information for existing responsible parties must be included in the ownership and operational history. "Financially viable" is generally defined as having sufficient financial resources to be able to perform part or all of the cleanup required at a particular property.

To qualify as a property within an EZ or Keystone Opportunity Zone (KOZ), the municipality where the property is located must be designated by DCED as an EZ, KOZ, or Keystone Innovation Zone (KIZ). To determine whether a particular property is within an EZ, KOZ, or KIZ, contact DCED or the appropriate local contact person. If a remediator wants to determine the eligibility of a site for the SIA provisions, when a financially viable responsible party is present, the remediator will need to verify the existence of the EZ, KOZ, or KIZ designation for the area where the site is located.

A letter from either DCED or the appropriate zone contact person should be provided with the work plan to verify the status of the property. Persons remediating a site in an EZ where a viable responsible party may still exist are only responsible for remediation of contamination identified in the baseline environmental report and specified in the CO&A with the Department as required for remediation prior to the new use of the property. Additional remediation may be pursued by the Department with the responsible person. Responsible persons under HSCA must resolve their liability to the Department pursuant to HSCA. See Section V.E of this manual.

c) Process Checklist for Special Industrial Areas

☐ Evaluate the property potential for redevelopment.

☐ Determine if the property was used previously for industrial activity or if it is located within an EZ (35 P.S. 6026.305(a) and 25 Pa. Code § 250.502).

☐ Determine if there is a financially viable responsible party. If the property is located within an EZ, financial viability is not a requirement for SIA use (35 P.S. 6026.305(a) and 25 Pa. Code § 250.502).

☐ The remediator must demonstrate to the Department that he did not cause or contribute to contamination on the property (35 P.S. 6026.305(a) and 25 Pa. Code § 250.502).

☐ Review the historical information and present use of regulated substances at the property.

☐ Prepare a work plan for a baseline remedial investigation (35 P.S. 6026.305(b) and 25 Pa. Code § 250.503(b)).

☐ The work plan must be approved by the Department prior to performing the investigation (35 P.S. 6026.305(b) and 25 Pa. Code § 250.503(b)).

☐ Begin baseline remedial investigation (use Section II.B.4.e of this manual, 35 P.S. 6026.305(b) and 25 Pa. Code § 250.503(c)).

☐ Submit NIR for the SIA to the Department. Also provide notice to the municipality, publish a notice of submission of the NIR in a local newspaper, and provide reasonable proof of required notices to the Department.

☐ Prepare public involvement plan (if requested by municipality).

☐ Prepare baseline environmental report based on baseline remedial investigation (35 P.S. 6026.305(b) and 25 Pa. Code § 250.503(d)).

☐ Department review of baseline environmental report.

☐ Meet with the Department and concur on CO&A. The prospective purchaser should enter into the CO&A prior to purchasing the property (35 P.S. 6026.305(e) and 502(a)).

☐ Remediate the property to the SIA requirements specified in the baseline environmental report and agreed to in the CO&A (35 P.S. 6026.502(b)).

☐ Calculate the mass of contaminants remediated using the procedure in Section III.C of this manual.

☐ Complete the Final Report Summary and submit electronically as per the instructions on the Land Recycling Program web page.

☐ Protection from liability occurs upon the signing of the CO&A with the Department, subject to the remediator's compliance with the CO&A demonstrating attainment of the SIA requirements in accordance with Chapters 3 and 5 of Act 2.

☐ Submit an environmental covenant, if applicable, to the Department.

d) Aspects of Special Industrial Areas

i) Immediate, Direct, or Imminent Threats to Human Health and the Environment

One of the significant aspects of Act 2 is the cleanup liability protection provided for SIAs. The cleanup liability for the person undertaking remediation and reuse of an SIA is dependent upon the person performing remediation of immediate, direct or imminent threats to public health or the environment which would prevent the property from being occupied for the remediator's intended purpose.

The immediate, direct, or imminent threats are to be determined by the baseline remedial investigation and defined in the baseline environmental report. The baseline environmental report will become the basis for the CO&A between the Department and the remediator. The exposures, and potential exposures, presented by an SIA site must be identified in the baseline remedial investigation. Defining immediate, direct, or imminent threats is relevant to the remediator's intended use of the property. Therefore, it is necessary for the remediator to specify the intended use of the property. The identification of these threats needs to be addressed at the time of the baseline remedial investigation work plan and in performance of the investigation. Only concerns identified in the baseline environmental report and included in the agreement can be considered in any relief from liability afforded to the remediator by Act 2. For this reason, it is paramount that the remediator performs a comprehensive investigation of an SIA.

Immediate and imminent threats are pending threats likely to happen without delay or momentarily in time. Direct threats, though sometimes similar in immediacy, also include chronic exposure. At a minimum, immediate, direct, or imminent threats will entail:

- Contained wastes which present immediate, direct or imminent threats. Examples are regulated substances in drums, barrels, tanks, or other bulk storage containers; and contained wastes, such as wastes in drums, above or below ground tanks, and small containers.

- All wastes which are not containerized, and which present a direct threat to workers or other persons on the property. These may include, but are not limited to, open containers, pits, waste piles and other situations that allow wastes to be exposed and accessible on the site.

- In addition to situations listed above, actual exposure for onsite human populations to any regulated substances.

- Actual contamination of drinking water by regulated substances. Also, contaminated groundwater, if groundwater use will expose persons on the property to contaminants.

- Contaminated soil presenting a direct contact threat to workers or other persons on the property. Direct contact may occur in a zone of soil at and below the surface. The depth of consideration of surface soil shall be the first two feet from the ground surface, unless reuse of the property presents exposure threats at depths greater than two feet.

- Regulated substances presenting a threat of fire or explosion.

- Surface water and sediments contaminated with regulated substances, if persons are or may become exposed to these contaminants.

- Regulated substances contained as product may remain on the property if maintained according to appropriate regulations. The remediator is responsible for releases occurring as a result of the remediator's actions.

ii) Consideration of Chronic Exposure in Evaluation of the Reuse of a Special Industrial Area

25 Pa. Code Section 250.503(c)(5) pertains to property to be reused and states, "Evaluation of exposure conditions within the portion of the property to be reused to identify existing contamination that poses an immediate, direct or imminent threat to public health or the environment which is inconsistent with the intended reuse of that portion of the property." Initially, the determination of property use for nonresidential or residential purposes will focus on determination of direct contact exposure. In the use of the definition of "immediate, direct or imminent," the word "direct" includes chronic exposure. In the scope of chronic exposure, workers or other persons using a property with existing contamination are to be protected from chronic exposure levels of contaminants as well as to acute exposure levels. Direct contact includes contamination which persons may come in contact with when working, living at, or visiting a site. Direct contact may occur by several routes. Some examples are ingestion of soil, contact with soil, or inhalation of soil particles or vapor from the soil. Additional direct contact pathways may be caused by leaching from the soil to groundwater, vapor intrusion into buildings, inhalation of contaminated process water, surface water run-off to water bodies, and exposure of wildlife and ecosystems. Soil available for direct contact must meet the human health and environmental protection standards established by Act 2.

iii) Contaminant Migration Off-Property

There are no obligations or liability for off-property contamination placed upon an innocent person using the SIA provision. For cases where the off-property pollution is significant, there may be other available options for addressing these risks. If there is an existing viable responsible party (property located within an EZ), the viable responsible party would continue to be responsible for off-property contamination. For sites where there is no viable responsible party, the cleanup may either be remediated by a purchaser of the property (voluntary cleanup) or addressed under other State or federal programs. In either case, the innocent purchaser would not be responsible for off-property contamination, as long as he or she did not cause or contribute to that contamination. Although assessment at the time of the baseline remedial investigation is not required off-property, the remediator should determine whether contamination is moving off the property.

If contamination which requires remediation is found at a future date, and the nature, concentration, and location were not identified in the baseline environmental report, the remediator may be liable to perform cleanup of the contamination to one of the three standards.

iv) Contamination Identified Subsequent to Remediation and Agreement Conditions

Under Section 502(b) of Act 2 the remediator is only relieved from liability for contamination which was identified in the baseline environmental report. For this reason, it is to the remediator's benefit to conduct a comprehensive investigation.

v) Storage Tank Closure and Corrective Action at Special Industrial Areas

Remediators are only responsible for addressing the immediate, direct or imminent threats posed at SIAs. In all cases this includes removal of waste in containers. Materials remaining in tanks must be removed and handled in accordance with applicable laws and regulations. Product may remain in the tanks if it is rendered inert and poses no risk. The actual tanks are required to be removed or rendered safe. The remediator should follow the Storage Tank Program regulations and guidance to achieve a safe closure of tanks. Smaller containers will likely be required to be removed. Releases from tanks that occur after the remediator becomes the owner or operator are the responsibility of the remediator.

vi) Consent Orders and Agreements

Remediation of all threats relevant to an SIA reuse which were detailed in the baseline environmental report will be detailed in a CO&A.

Contamination not identified in the baseline environmental report will become the responsibility of the remediator.

A change in use of the property, from that defined in the Agreement, may necessitate a change in the Agreement or modification of the proposed property reuse. A land use change for an SIA may trigger a reopener under Section 505(4) of Act 2. The CO&A with the Department will require the remediator or reuser to provide the Department with written notice of any change in the use of the property and to remediate any contamination which would prevent the use of the property for its new purpose.

vii) Remediation

Remediation in SIAs must meet the following requirements:

- Cleanup may utilize treatment, containment, removal, control methods, or any combination of the above.
- Cleanup must address all containerized waste at the property in accordance with applicable regulations.
- Soil available for direct contact must meet one of the three remediation standards.
- Cleanup of any wastes or cleanup of any medium contaminated with regulated substances which pose an immediate, direct, or imminent threat to human health or the environment based on the intended use of the property must be to one of the three remediation standards.

If groundwater is to be used at the property, the groundwater must either be remediated in-ground or at the point of use so that it is safe for its intended use and occupation of the property.

viii) Environmental Covenant

An environmental covenant is necessary for SIA remediations that require an activity and use limitation. The environmental covenant may also fulfill any deed acknowledgement requirements specified by SWMA and HSCA. Future activity and use limitations due to disposal of hazardous wastes or regulated substances may be required as part of the remedy and may be identified as part of the environmental covenant.

e) Work Plan for Baseline Remedial Investigation and Baseline Environmental Report

i) Work Plan for Baseline Remedial Investigation

A baseline remedial investigation is required for evaluation of a property that will be part of an SIA agreement. The objective of the baseline remedial investigation is to establish a reference point documenting contamination that existed prior to the redevelopment. A work plan for the baseline remedial investigation is required to be prepared by the remediator and approved by the Department prior to initiation of the investigation. The findings and conclusions of the baseline remedial investigation shall be documented in a report known as a baseline environmental report.

The work plan for the baseline remedial investigation shall be designed considering the unique considerations of SIAs and tailored for the specific property. The work plan shall address how the remediator will perform the baseline remedial investigation and shall address the items below and any additional items determined to be appropriate by the person proposing remediation or requested by the Department. The work plan for the remedial investigation shall include the steps to be taken to document the following:

- A description of the property and detailed ownership history.

- Identification of the historical regulated substance use, handling and disposal activities on the property, and any known or suspected releases associated with these activities. This is obtained by conducting an environmental site characterization, a review of historical records, and interviews with persons who may have knowledge of the property.

- Characterization of the regulated substances on the property. Identification of existing contamination that poses an immediate, direct or imminent threat to public health or the environment which would prevent the property from being occupied for the intended use.

- Identification of potential migration pathways off the property, or onto the property, and any potential receptors from any release on the property. Where migration pathways and receptors have been identified, the remediator shall perform environmental sampling of the groundwater at the downgradient property boundary to determine if regulated substances from releases on the property have migrated off the property.

- In addition to the above, environmental sampling, if indicated by the investigation, in all potential media of concern to confirm whether releases have occurred.

ii) Baseline Environmental Report

The baseline environmental report shall provide the results of the baseline remedial investigation and describe the historical use, location of areas of contamination, the intended reuse, sampling results, contaminant migration occurrence or potential, and the proposed remediation measures to ensure that the SIA requirements are met. Portions of the baseline environmental report containing information about geologic or hydrogeologic investigations shall be prepared and certified by a registered professional geologist licensed in Pennsylvania. The baseline environmental report shall be submitted without binding. The following is a recommended scope of a baseline environmental report:

Summary: Provide a summary paragraph(s) that will give the reviewer an overview of the property. This will serve to highlight the important issues and conclusion that will be presented in the report.

Description of Property: Provide a description of the property in sufficient detail to give the reader an overall idea of the property and its location. Describe the following:

- Buildings and other site features such as lagoons, tanks, treatment plants, and other structures on the property. Include a site map (scale of 1 inch = 200 feet).

- The location of all onsite wells, septic systems, floor drains, sumps and associated piping, storage areas, and chemicals or chemical compounds used, stored, treated or disposed.

- A description of present conditions at the property including any evidence of a release, contaminated media, tanks, and identification of areas of uncontained and/or SPL.

- The location and name of any public or private water supply on or near the property.

- The location, name and elevation of surface water bodies (springs, streams, lakes, ponds, wetlands) within 2,500 feet of the property.

- The location of utility lines at and near the area of investigation including any municipal or private water supply lines or natural gas lines, sanitary or sewer lines, and any other subsurface utilities.

- The location of active and inactive oil and gas wells, injection wells, surface and underground coal and non-coal mines, mine

pool discharge points, landfills, and surface disposal areas within 2,500 feet of the property.

- Identify sensitive features within 2,500 feet of the property, such as threatened or endangered species habitat, recreational river corridors, state and federal forests and parks, historic and archaeological sites, national wildlife refuges, state natural areas, prime farm land, wetlands, special protection watersheds designated under Chapter 93 and other features.

Ownership History: Provide a detailed property ownership history since the release of regulated substances onsite. Include company or individual name and address (if available), ownership period, and the general operational use of the property during each ownership period.

Site Use History: Provide detail on past and current uses of property and adjoining properties; including treatment, storage, and disposal of regulated substances. Indicate the type, estimated volume, composition, and nature of the released materials, chemicals or chemical compounds. Indicate the sources of regulated substances; description of spills, leaks, releases on the property; and migration or migration potential to adjacent properties; and remedial action to date. Include a brief description of agency actions such as violation notices, administrative orders, and environmental permits.

Site Characterization: The site characterization provides important information documenting the current conditions at the property. Information developed during the site characterization is primarily intended to describe the nature, extent, and potential for movement of all contaminants present on the property, or that may have migrated from the property. For sites where there are multiple distinct areas of contamination, the site characterization process should be applied to each area individually. The remediator must use scientifically recognized principles, standards and procedures.

Geology/Hydrogeology: Description should be based on existing literature and data (Soil Classification System (SCS) soil surveys, geologic maps, Water Resource reports, reports on nearby properties and sampling) including:

- Descriptions of the soils, fill materials, geologic, hydrologic and hydrogeologic conditions at and surrounding the property. These descriptions should be detailed enough to provide an understanding of the site with respect to local geologic conditions and to determine if property groundwater is in an aquifer as defined by Act 2.

- A local stratigraphic column including lithology, physical characteristics and the approximate thickness of each stratum, include location and depth of aquifer(s) (if known).

- The geologic structure within the property boundaries and its relation to the regional geologic structure (if known).

- The location(s) of sinkholes, fracture traces, outcrops, and lineaments (if known).

- Screening of soils, sediments and water (as appropriate). Submit all results, include QA/QC documentation. Identify field screening methods and sampling procedures. Cone Penetration Technologies (CPT) and other direct push technologies (DPT) may be used for sampling of solids, soil gases, and groundwater. CPT and DPT results should be useful to more accurately site permanent monitoring wells in areas of concern. Vapor intrusion assessments should be conducted in accordance with Section IV of this manual. All sample locations should be depicted on a site map. Incorporate results from past sampling, if applicable.

Soil investigations shall be performed to establish baseline quality of surface, shallow, and subsurface soils at the site. Investigations will involve actual, as well as potential, sources of contamination, underground storage tanks, stained soils, and building drains, sumps, and storm/sewer systems. Investigations of underground storage tanks will identify any potential impacts from possible leakage of the tanks. Sampling will be performed. Property boundary soil sampling may also be performed to assess soil quality conditions and compared to the appropriate residential or nonresidential standards based on the proposed use of the property. Groundwater investigations shall be performed to establish baseline quality of the shallow and aquifer groundwater conditions. Investigations will involve wells (both monitoring and supply, and including appropriate off-property wells), sample analysis and water quality, and groundwater level measurement.

Identified Contamination: Characterize the source and nature, concentration, location, and extent of the regulated substances. Text, tables, graphics, figures, maps and cross sections may be used to describe the nature, location, and composition of the contaminants on the property. Determine the extent, if any, of regulated substances that have migrated beyond the property boundary. Indicate all existing and potential migration pathways. Indicate the direction and rate of contaminant movement within each medium of concern.

Proposed Remediation Measures: The baseline environmental report shall include the proposed plan for remediation of the property and will serve as the basis for the CO&A. Therefore, the remedial action must be fully defined and described. The remediation of all threats relevant to the

special industrial area reuse will be reiterated in the CO&A. Identification of contamination is very important in establishing what the remediator will be obligated to cleanup, and the extent of the cleanup liability protection afforded by Act 2.

Public Notice: Provide information concerning all public notifications performed. Supply copies of the notifications and reasonable proof of required notices of the NIR in a newspaper of general circulation serving the area where the property is located. Indicate if a municipality requested a public involvement, and if so, include the public involvement plan and all comments received, and responses to those comments.

Public Benefits: The baseline environmental report should include a description of the existing or potential public benefits of the use or reuse of the property for employment opportunities, housing, open space, recreation or other uses. An estimate of the potential employment anticipated by the reuse of the property is also requested.

Signatures: If any portion of the submitted report were prepared or reviewed by or under the responsible charge of a registered professional geologist or engineer, the professional geologist or engineer in charge must sign and seal the report.

Attachments:

Attachments may include but are not limited to:

- Tables – monitoring well construction summary, groundwater gauging data (including elevation and NAPL thicknesses), analytical data, historical data.
- Figures – including groundwater elevation maps, extent of NAPL, concentration data for soil/groundwater/surface water/vapor or indoor air, cross-sections.
- Monitoring well construction diagrams, boring logs, stratigraphic logs, including soil/rock characteristics.
- Sampling and analysis plan(s).
- QA/QC Plan.
- Ecological survey documentation (from PNDI).
- Well search documentation (from PaGIS).
- Field data sheets, such as low flow purging monitoring.

- Statistical worksheets, software outputs, graphs; modeling inputs/outputs.
- Disposal documentation of soil/groundwater.
- Remediation system operation, maintenance, monitoring data; mass removal estimates.
- Before and after remediation photographs.
- Copy of municipal notification, reasonable proof of newspaper notice publication.
- Laboratory reports and any voluminous attachments may be enclosed on a CD.

APPENDIX

Appendix II-A: The Use of Caps as Activity and Use Limitations

Caps are one of the most common mechanisms used by remediators to eliminate exposure pathways at sites with subsurface contamination. As the term is used in this document, caps encompass a broad array of physical features that cover underlying contamination. Capping prevents exposure via direct contact by acting as a barrier between a human receptor and the underlying contaminated media. Low permeability caps can also help limit vertical movement of contaminants via stormwater infiltration or vapor migration. Different caps work more effectively in certain situations, so site-specific information should be used to determine which cap system to select.

The conceptual site model (see the site characterization discussion in Section II of this manual) should be used to identify potential receptors and related contaminant migration and exposure pathways. The receptors and pathways to be addressed should be evaluated before cap construction takes place to ensure that installation of the cap will achieve the desired result. Remediators should clearly understand the nature and extent of contaminants at their site and the current and projected future conditions.

The guidance provided in this addendum applies solely to the use of caps in attaining an Act 2 standard. Caps used at landfills, RCRA sites, or other non-Act 2 sites may have requirements that differ from the guidance provided in this addendum and should follow the relevant regulations of the program/entity regulating the facility. Additionally, this addendum is intended to supplement existing guidance; it is not regulation and should not be interpreted as such. This addendum is provided to inform remediators of pertinent information to consider when selecting cap systems and some of the options that are available. Remediators may choose to consider alternative technologies other than those discussed herein when addressing their specific situation. Remediators may need to develop a different approach than what is described in this guidance to provide the best fit for their specific situation.

A cap is a barrier over contaminated media that eliminates an exposure pathway, controls contaminant migration, or a combination of both. Thus, a cap can be used as an engineering control and/or an institutional control (i.e., an activity and use limitation) to attain an Act 2 standard. As such, remedies that use a cap require a cleanup plan which describes the selected remedy. If a cap already exists at the site (e.g., a parking lot) and needs to be preserved as part of the remedy, then the cleanup plan should describe the way the cap will be maintained. Since a cap is used as an activity and use limitation, a remediator must properly record an environmental covenant pursuant to the Uniform Environmental Covenants Act to ensure the cap is properly maintained in the future. If applicable, the final report should include as-built plans and details of the cap construction and photographs documenting installation of the cap, when available. The post-remediation care plan and environmental covenant should include a map depicting the extent of the cap as well as monitoring and maintenance requirements.

All components of cap utilization for the purpose of attaining an Act 2 standard, including but not limited to, design, construction, and inspection, may be governed by the Engineer, Land Surveyor, and Geologist Registration Law (63 P.S. §§ 148-158.2).

General Goals for Caps – Caps are generally used to address contamination at concentrations resulting in an unacceptable risk for the following purposes:

- Protection from direct contact with contaminated soil.

- Prevention or reduction of the migration of contamination throughout the subsurface (upward, downward, and laterally).

- Prevention of the migration of contamination to surface water via stormwater runoff.

Cap Construction Considerations – The following factors should be considered during the design, construction and maintenance of most caps, where appropriate:

- Erosion from precipitation, surface water flow or wind.

- Cracking and deterioration from natural influences including water saturation and freeze/thaw cycles.

- Expected human activities on the land covered by the cap.

- Settlement and shifting of the cap and subsurface.

- Potential damage from migration of groundwater into the cap.

- Contaminant migration, including migration to the surface of the cap and potential vapor migration. Refer to Section IV of this manual when evaluating the vapor intrusion pathway.

- Construction impacts to site development including storm water management.

Protection from Direct Contact with Contaminants

Design Goals – In addition to the cap construction considerations presented previously, the design should prevent direct contact exposure to contaminated soil for as long as the contaminant concentrations remain at unacceptable levels. Cap designs should consider site-specific factors, including, but not limited to:

- Current and anticipated future land use (anticipated future activities that could result in creating an exposure pathway to the soil should be addressed with land use restrictions).

- The nature of the contaminants (concentrations, mobility, toxicity, etc.).

- The types of potential exposure pathways (e.g., ingestion or inhalation).

- Contaminant degradation and daughter products resulting from such degradation, if any.

- The specifications of the capping material, the quality control of the cap construction, and the operation and maintenance (O&M) and inspection requirements.

- The reliability of the assurances that O&M, and inspections will be performed for as long as direct contact exposure to, or migration through or from the contaminants in soil beneath the cap would result in an unacceptable risk.

Soil Caps – Soil caps can be used to prevent direct contact exposure to contaminated soils. Soil containing regulated substances, at concentrations that do not constitute an unacceptable risk to human health by the direct contact pathway may be used as cap material. Cap thickness depends on various factors including the type and intensity of the land use above the cap and the contours/slope of the area being capped.

In general, it is recommended that caps used to prevent direct contact with contaminated soil are constructed with two feet of acceptable soil including a vegetated cover to prevent erosion and deterioration. The vegetated cover usually consists of six inches of topsoil, with appropriate seeding or sod to establish a good growth of grass. When a vegetated cover is used, consideration can be given to reducing the thickness of the acceptable soil layer by the same amount as the vegetated cover thickness (e.g., 1.5 feet of acceptable soil with an additional six inches of topsoil for a total cap thickness of two feet).

Cap designs of less than two feet thickness may be appropriate when additional design features, such as the use of warning fabrics, are considered or if the likelihood of deterioration is low (e.g. flat surfaces, low foot/vehicle traffic, etc.). Other materials, such as gravel, may substitute for vegetated topsoil as discussed below. Capping materials should be durable and meet the performance specifications required for the site.

DEP recommends placement of a demarcation boundary (warning fabric) on top of the contaminated soil and beneath the soil cap. The slope for an acceptable soil cap with vegetated topsoil cover should normally not be steeper than a 3:1 horizontal-to-vertical ratio. Steeper slopes may be considered on a case-by-case basis if it can be shown that erosion will be adequately controlled through additional design features and/or O&M. Steeper slopes will generally call for an evaluation of the need for slope reinforcement to provide long- term stability. However, cap design should use lower slopes when possible and good cover vegetation to slow down stormwater runoff velocities to prevent erosion. If cap material is suspected to have been impacted by a release, remediators should demonstrate that the material was evaluated using DEP's Management of Fill Policy (DEP ID 258-2182-773).

Pavement covers – Pavement systems may be used to prevent direct contact exposure to contaminated soils. Contaminated soil particles can work their way up through pavement surfaces where pavement settlement, shifting, cracking, freeze/thaw cycles, weathering, and deterioration are not adequately addressed in the design, construction, and maintenance of the cap. Pavement material should have appropriate bottom base soil preparation (grading, recompaction, dewatering, etc.) and sufficient base course to minimize freeze/thaw, settling, and shifting problems, which can cause pavement deterioration. Pavement thickness and overall design can be determined based on normal paving procedures to ensure structural integrity. Generally accepted pavement construction guidance sources should be used such as the American Association of State Highway Transportation Officials.

Buildings or Structures – An existing or new building or structure may be used to prevent direct contact exposure to contaminated soils, provided the building slab or basement walls/floor are evaluated for the general cap construction considerations discussed previously. Buildings with badly cracked slabs or basement floors or walls in contact with contaminated soil should be repaired. Dirt floors in buildings should be treated like any other portion of the site with bare soils.

Other Materials – The following materials, by themselves, might not be acceptable for a direct contact cover system because of the potential for contaminated soil to migrate through them. However, they

may be substituted for the vegetated topsoil portion of the soil direct contact cover system using the thickness indicated:

- Gravel or stone – A layer of gravel or stone thick enough to prevent erosion (usually six inches) is recommended.

  Note: A permeable cap constructed entirely of gravel/stone may be used to prevent direct contact if a mixed grade of aggregate is used and the layer of aggregate will pack sufficiently tightly to keep soils from migrating upward or, if the gravel/stone is used in combination with a geotextile layer to prevent soil particle migration and adequate maintenance is provided to retain the intended thickness of the cap.

- Geomembranes – A synthetic membrane liner made from thin continuous polymeric sheets is acceptable if the material is not considered an untreated geotextile. Geomembranes constructed from low density polyethylene (LDPE), high density polyethylene (HDPE), or polyvinyl chloride (PVC), are generally acceptable. If the geomembrane is not buried beneath a soil cover, resistance of the material to degradation from exposure to ultra-violet light must be considered in the design and postremediation care plan.

- Geotextiles – A woven or nonwoven geotextile is not acceptable for a direct contact cover by itself except as a very short-term temporary cover to prevent erosion. A geotextile layer may be used to:

  - Prevent contaminated soil particles from migrating to layers with concentrations of regulated substances that do not constitute an unacceptable risk.

  - Provide a demarcation layer between the cap material and contaminated soil.

  - Provide physical reinforcement and enhanced stability.

  Note: Use of a geotextile warning fabric is encouraged for sites where future construction or utility work is anticipated.

Horizontal Extent of Cap – The cap should be designed and constructed to provide adequate protection from exposure to all areas that have contaminant concentrations that do not meet an acceptable risk level. The cap design thickness should extend horizontally to a perimeter line beyond where unacceptable contamination has been delineated to ensure adequate protection from direct contact.

Prevention of Migration of Contaminants

Design Goals – If the control of contaminant movement is necessary to meet the chosen Act 2 standard, the cap design should minimize the migration of contaminants from contaminated soil to groundwater or to the surface via soil moisture or vapor migration. The cap construction considerations presented previously should also be considered for caps designed to prevent contaminant migration. The transport of chemicals to receptors of concern could occur via upward or downward movement of dissolved contamination in soil moisture and from volatile contaminant movement upward and downward in soil gas by vapor diffusion or bulk soil-gas flow. The cap may require features to control these modes of transport. If the infiltration of surface water, precipitation, or snow melt through contaminated soil needs to be significantly minimized, then the cover system should include a layer or layers that reduce

such infiltration to the extent necessary to achieve the required minimization. The design of these types of cap systems should consider site-specific factors, including, but not limited to:

- The nature of the contaminants (concentrations, degradation, solubility, mobility, toxicity, etc.).
- Depth of the contamination. (Note: The horizontal extent of the cap may need to extend beyond the direct contact footprint to address contamination in deeper soil horizons.)
- The quality of construction and the operation, maintenance and inspection program for the site.
- The reliability of O&M and inspections to maintain the remedy for as long as the unacceptable soil contaminant concentrations persist.
- Construction impacts to site development including storm water management.

Low-permeability Cap Designs – Typical materials used in the construction of low-permeability caps for reducing water infiltration include, but are not limited to, geomembranes, engineered mixtures of properly compacted fine sand, silt and clay, clay barriers, geosynthetic clay liners, concrete, and pavement. Typical materials used in the construction of vapor barriers include plastic membranes made of polyethylene or propylene, and semisolid barriers that are applied by spraying or pumping.

Buildings or Structures – An existing or new building or structure may be used to prevent infiltration into contaminated soils provided the building has a sound roof and roof runoff is managed to minimize runoff infiltration into contaminated soils. Dirt floors in buildings should be treated like any other portion of the site with bare soils. The potential for vapor intrusion into buildings should be evaluated in accordance with the guidance provided in Section IV of this manual.

Multiple Pathway Designs – A cap that meets the requirements for prevention of infiltration will likely be acceptable for prevention of direct contact. All cap systems should be designed and evaluated for the pathways being addressed.

Horizontal Extent – The guidance provided previously on the horizontal extent of cap designs for protection against direct contact exposure also applies to the prevention of contaminant migration to groundwater using the applicable groundwater protection standards.

VOC (Volatile Organic Compounds) Migration – VOC concentrations in soil and shallow groundwater may be a source of contaminant vapors that can migrate, transporting the VOCs to locations that may not be currently contaminated. Certain types of caps, such as pavement, may limit the upward vertical migration of vapors to the surface but may force them to migrate horizontally to create new contamination in soil and groundwater. The cap may also direct vapors into buildings, increasing indoor air contaminant concentrations. Vapors could migrate into the cap itself contaminating the previously acceptable material and potentially damaging it (for example, certain VOCs can degrade asphalt or kill vegetation). It may be necessary to treat or remove the sources of vapors or provide active or passive venting below and/or adjacent to a cap to remove soil vapors and prevent vapor migration.

Inspections and Maintenance

Post-remediation care plans (PRCPs) and environmental covenants must contain appropriate conditions to ensure that the integrity of the cap is maintained if the cap is used to attain an Act 2 standard. Please

refer to Section III.E of this manual for information on long-term stewardship obligations for post-remediation care plans and environmental covenants. Factors to consider and DEP's recommended best practices include the following:

- The extent of the cap should be well defined such that the owner, contractors, DEP, and other parties can readily identify the restricted area. The cap boundaries should be clearly marked on a map or site figure.

- A professional survey of the cap boundaries is beneficial, for instance when the cap is not readily visible, landmarks used to define the boundaries change, the cap area is large, or the cap boundaries are irregular.

- Caps should be inspected periodically depending on how likely they are expected to require routine maintenance and the potential risks from cap disturbance. In cases where caps are more likely to experience disturbance (e.g., on sloped surfaces or in high-use areas), inspections should be more frequent.

- Inspections should take place during and after any activities that disrupt or penetrate the cap, such as landscaping work, utility trenching, and construction.

- All inspections should be recorded in writing. Photographs are useful documentation of the cap condition. Inspection records should be maintained for a period of three years and must be made available for DEP review upon request.

- Contractors should consider the need to develop a health and safety plan to address potential future exposures to contaminated soil beneath the cap by construction and utility workers.

- Qualitative or quantitative criteria may be developed in the PRCP to determine when disruptions to cap integrity that could impair its effectiveness must be repaired.

- Disruptions of soil caps, including excavation, removal, penetration, erosion, loss of vegetated topsoil, or any other cumulative thinning of the original cap thickness, should be repaired within 30 days of the date of discovery.

- Disruptions of pavement, buildings, and other structural caps, including removal, penetration, significant cracking, erosion, or other opening(s), should be repaired within 30 days of the date of discovery.

Both the discovery and repair of cap disruptions should be reported to DEP as required by the PRCP and environmental covenant within one month of discovery. The reporting should describe the nature and cause of the disruption, explain the corrective actions taken, and document that repairs were made (e.g., photographs).

ATTACHMENT C

PADEP Management of Fill Policy and Clean Fill Certification Form

DEPARTMENT OF ENVIRONMENTAL PROTECTION
Bureau of Waste Management

DOCUMENT NUMBER: 258-2182-773

EFFECTIVE DATE: January 16, 2021

TITLE: Management of Fill Policy

AUTHORITY: This document is established in accordance with the Solid Waste Management Act, 35 P.S. §§ 6018.101 *et seq.* (SWMA); the Clean Streams Law, 35 P.S. §§ 691.1 *et seq.*; Section 1917-A of the Administrative Code, 71 P.S. § 510-17; and the Land Recycling and Environmental Remediation Standards Act, 35 P.S. §§ 6026.101 *et seq.*

POLICY: A person placing solid waste onto the ground is generally required to obtain a disposal permit from the Department of Environmental Protection (Department or DEP). A person is not required to obtain a permit under SWMA if the person can demonstrate that the material qualifies as clean fill in accordance with the municipal and residual waste regulations, 25 Pa. Code § 271.101(b)(3) and § 287.101(b)(6).

PURPOSE: This policy provides DEP's procedures for determining whether fill is "clean fill," as defined in the municipal and residual waste regulations at 25 Pa. Code § 271.1 and § 287.1, respectively, or "regulated fill," as defined in this policy. Regulated fill may not be used outside of a project area or right-of-way of a project unless a SWMA permit has been issued to the person using the regulated fill.

APPLICABILITY: This policy shall be used to evaluate whether a person is required to obtain a permit under the SWMA for the use of fill in accordance with the municipal and residual waste regulations, 25 Pa. Code § 271.101(b)(3) and § 287.101(b)(6). This policy describes the type of fill that qualifies as clean fill or regulated fill. This policy does not apply to mine land reclamation activities subject to a permit or fill used within the same project area or project right-of-way. Excavation, movement or reuse of fill within a project area or right-of-way of a project is not an activity that requires a SWMA permit. This policy does not apply to fill that has been determined to be clean or regulated fill prior to the effective date of this policy, unless the fill is moved to a new receiving site or off the project area or project right-of-way after the effective date of this policy. This policy does not apply to fill that has been determined to be clean or regulated fill prior to the implementation of revised clean fill concentration limits or regulated fill concentration limits, unless the fill is moved to a new receiving site or off the project area or project right-of-way after the effective date of the revised limits.

DISCLAIMER: The policies and procedures outlined in this guidance document are intended to supplement existing requirements. Nothing in the policies or

procedures shall affect regulatory requirements. The policies and procedures herein are not an adjudication or a regulation. There is no intent on the part of the DEP to give the rules in these policies that weight or deference. This document establishes the framework within which DEP will exercise its administrative discretion in the future. DEP reserves the discretion to deviate from this policy statement if circumstances warrant.

PAGE LENGTH: 26 pages

DEFINITIONS:

Acid-producing rock – Stone, rock or other mineral materials that, when exposed to air and water, cause a low pH discharge that adversely affects or endangers public health, safety, welfare, or the environment or causes a public nuisance.

Act 2 – The Land Recycling and Environmental Remediation Standards Act, 35 P.S. §§ 6026.101 *et seq.*

Act 2 site – A site as defined in Section 103 of Act 2, 35 P.S. § 6026.103, for which a notice of intent to remediate has been submitted to DEP.

Background – The concentration of a regulated substance that is present at a site but not related to the release of regulated substances from a specific point source or activity at the site.

Background reference area – The area identified for sampling that: will be used to establish background; is sampled and analyzed to determine the concentration of regulated substances found at or within a close proximity to the donor site, at a depth comparable to that of the area to be excavated at the donor site, in the same soil layer as the donor fill; is unaffected by a release of regulated substances from a specific point source or activity at the site; and meets one of the following criteria:

i. The concentration of regulated substances in the soil is attributable to the parent material from which the soil was derived and the natural processes which produce soil, or

ii. The concentrations of regulated substances in the soil resulted from an atmospheric deposition, including lead or polynuclear aromatic hydrocarbons, but are not attributable to a specific point source or release of a regulated substance. For the purposes of this definition, "atmospheric deposition" refers only to the ubiquitous, widespread deposition of regulated substances from the air that is incapable of being traced to a specific point source or multiple point sources. For example, chromium that has condensed on the ground outside an electroplater air vent would not be due to "atmospheric deposition" because the presence of the chromium is a result of a discharge from a specific point source, even though the chromium was released into the air before being deposited on the ground. However, the presence of lead or benzo-a-pyrene (BAP) in an urban or industrial area that can be traced to the operation of motor vehicles may be due to atmospheric deposition if the concentration levels are demonstrated to be pervasive over the greater urban or industrial area.

Clean fill – Uncontaminated, nonwater-soluble, nondecomposable, inert solid material used to level an area or bring an area to grade. The term does not include materials placed in or on the waters of the Commonwealth. Although the placement of clean fill in or on waters of the Commonwealth cannot be managed under this policy, placement of clean fill in or on waters of the Commonwealth may be approved under a separate DEP authorization. The term includes only those materials that are identified as "fill," as the term is defined in this policy. The term does not include fill that has been blended, mixed or treated with the purpose of meeting the definition of "clean fill" and that without being blended, mixed or treated would fail to meet the numeric limits identified in the definition of "uncontaminated material" contained in this policy.

Clean fill concentration limits (CFCLs) – With the exception of PCBs and chloride, the concentrations of regulated substances that do not exceed the numeric values specified in Table 3 [Medium-Specific Concentrations (MSCs) for Organic Regulated Substances in Soil] and Table 4 [Medium-Specific Concentrations (MSCs) for Inorganic Regulated Substances in Soil] of Appendix A in 25 Pa. Code

Chapter 250 (relating to administration of land recycling program). The applicable numeric limit is determined by comparison of the Generic Soil to Groundwater Value[1] with the Direct Contact Residential Value[2] and selection of the lower of the two values. For PCBs, the sum total of the concentration of all PCB aroclors (total PCB concentration) may not exceed 50 ppm. Fill containing a concentration of total PCBs greater than 2 ppm may be subject to regulation under the Toxic Substances Control Act (TSCA), 15 U.S.C. Section 2601 et seq., and 40 C.F.R. Part 761, which is administered and implemented by the U.S. Environmental Protection Agency (EPA). EPA's TSCA requirements are independent of any use of fill that is otherwise in accordance with the Department's policy and regulations. An applicant should be aware that its characterization and handling of any soils through the guidance of the Management of Fill policy does not necessarily satisfy a potential EPA TSCA inquiry, and that an applicant may need a separate approval from EPA should EPA require it. For all such material, DEP recommends that you contact the PCB Coordinator for EPA Region 3 by email at R3_PCB_Coor@epa.gov to determine whether PCB-containing fill may be used and to obtain information relating to the associated EPA procedures for collecting and analyzing samples. For chloride, the value obtained using the Synthetic Precipitation Leaching Procedure, (SPLP, SW-846, Method 1312) may not exceed the numeric value specified in Table 2 [MSCs for Inorganic Regulated Substances in Groundwater] of Appendix A in 25 Pa. Code, Chapter 250.

Composite sample – A sample collected across a spatial range that typically consists of a set of discrete samples that are combined or "composited." A composite sample should not be confused with a discrete sample that is created from multiple increments taken at a single location to obtain a sample of the desired size, shape and orientation.

Discrete sample – A sample that represents material from a single location. A discrete sample can be composed of more than one increment.

Donor site – The area from which fill originates that is separate from a receiving site. Multiple donor sites may be identified on a single project area.

Environmental due diligence – Investigative techniques used to determine whether fill from a donor site has been affected by a release of a regulated substance. Examples of investigative techniques included in this term are visual property inspections, electronic data base searches, review of ownership and historical use of a property, Sanborn maps, environmental questionnaires, transaction screens, analytical testing, environmental assessments, audits, or procedures outlined in ASTM standard E1527-13. A single investigative technique may not be used as the basis for environmental due diligence. Environmental due diligence includes visual property inspection and a review of ownership and historical property use, at a minimum, unless analytical sampling is performed in lieu of a review of ownership and historical property use.

Fill – The term is limited to clean, regulated and historic fill that is soil, rock, stone, gravel, used asphalt, brick, block or concrete from construction and demolition activities that is separate from other waste and recognizable as such, and "dredged material," as the term is defined by the municipal and residual waste regulations, 25 Pa. Code §§ 271.1 and 287.1, whichever is applicable. The term does not include reclaimed asphalt pavement, naturally occurring asbestos, mine spoils or acid-producing rock.

Grab sample – A discrete sample, consisting of one increment, collected specifically for Volatile Organic Compounds (VOC) analysis.

---

[1] Numeric values based on generic leaching modeling for soils at residential properties overlying used aquifers with total dissolved solids at concentrations less than or equal to 2500 mg/L.

[2] Direct contact numeric values for soils at residential properties.

Historic fill – Material, excluding material disposed in landfills, waste piles and impoundments, used to bring an area to grade prior to 1988, and consisting of a conglomeration of soil and residuals, such as ashes from the residential burning of wood and coal, incinerator ash, coal ash, slag, dredged material and construction and demolition waste. The term does not include iron or steel slag that is separate from residuals if it is a coproduct, as the term is defined in 25 Pa. Code § 287.1 and satisfies the requirements of 25 Pa. Code § 287.8. The term does not include coal ash that is separate from residuals if it is beneficially used in accordance with 25 Pa. Code §§ 290.1 – 290.415.

Increment – Material collected in a single operation of the sampling device.

PCB – A chemical substance that is limited to the biphenyl molecule that has been chlorinated to varying degrees or a substance that contains that substance.

ppm – Parts per million.

Project area – The boundary within which earth disturbance activities occur, including areas in close proximity to the earthmoving activities that are necessary for the completion of a construction project, or other human activity which disturbs the surface of the land, including land clearing and grubbing; grading; excavations; embankments; land development; agricultural plowing or tilling; operation of animal heavy use areas; timber harvesting activities; road maintenance activities; linear projects such as utility line work; oil and gas activities; well drilling; mineral extraction; and the moving, depositing, stockpiling, or storing of soil, rock or earth materials. The term includes the boundary within which all earth disturbance activity, construction, materials storage, grading, landscaping and related activities occur.

Reclaimed asphalt pavement (RAP) – Small particles, typically less than one inch in size, of bitumen and inorganic materials produced by the mechanical grinding of bituminous pavement surfaces that have not been subject to a release of regulated substances or mixed with other solid waste. The term does not include "used asphalt," as the term is defined in this policy.

Receiving site – The area to which fill is proposed to be relocated. A receiving site is separate from a donor site and not part of a project area or right-of-way.

Regulated fill – "Fill," as the term is defined in this policy, that has been affected by release of a regulated substance and is not "uncontaminated material," as the term is defined in this policy. The term does not include fill that has been blended, mixed or treated with the purpose of meeting the definition of "regulated fill" and that without being blended, mixed or treated would fail to meet the regulated fill concentration limits, as the term is defined in this policy.

Regulated fill concentration limits (RFCLs) – With the exception of PCBs, the concentrations of regulated substances that do not exceed the numeric values specified in Table 3 [Medium-Specific Concentrations (MSCs) for Organic Regulated Substances in Soil] and Table 4 [Medium-Specific Concentrations (MSCs) for Inorganic Regulated Substances in Soil] of Appendix A in 25 Pa. Code Chapter 250 (relating to administration of land recycling program). The applicable numeric limit is determined by comparison of the Generic Soil to Groundwater Value[3] with the Direct Contact Non-Residential Value[4] and selection of the lower of the two values. For PCBs, the sum total of the

[3] Numeric values based on generic leaching modeling for soils at non-residential properties overlying used aquifers with total dissolved solids at concentrations less than or equal to 2500 mg/L.
[4] Direct contact numeric values for soils at non-residential properties.

concentration of all PCB aroclors (total PCB concentration) may not exceed 50 ppm. Fill containing a concentration of total PCBs greater than 2 ppm may be subject to regulation under the Toxic Substances Control Act (TSCA), 15 U.S.C. Section 2601 et seq., and 40 C.F.R. Part 761, which is administered and implemented by the EPA. EPA's TSCA requirements are independent of any use of fill that is otherwise in accordance with the Department's policy and regulations. An applicant should be aware that its characterization and handling of any soils through the guidance of the Management of Fill policy does not necessarily satisfy a potential EPA TSCA inquiry, and that an applicant may need a separate approval from EPA should EPA require it. For all such material, DEP recommends that you contact the PCB Coordinator for EPA Region 3 by email at R3_PCB_Coor@epa.gov to determine whether PCB-containing fill may be used and to obtain information relating to the associated EPA procedures for collecting and analyzing samples.

Regulated substance – The term includes hazardous substances and contaminants regulated under the Hazardous Sites Cleanup Act, 35 P.S. §§ 6020.101 *et seq.*; and substances regulated by the Clean Streams Law, 35 P.S. §§ 691.1 *et seq.*; the Air Pollution Control Act, 35 P.S. §§ 4001 *et seq.*; the Solid Waste Management Act, 35 P.S. §§ 6018.101 *et seq.*; the Infectious and Chemotherapeutic Waste Law, 35 P.S. §§ 6019.1 *et seq.*; and the Storage Tank and Spill Prevention Act, 35 P.S. §§ 6021.101 *et seq.*

Release – Spilling, leaking, pumping, pouring, emitting, emptying, discharging, injecting, escaping, leaching, dumping or disposing of a regulated substance into the environment in a manner not authorized by the Department. The term includes the abandonment or discarding of barrels, containers, vessels and other receptacles containing a regulated substance.

Uncontaminated or *Uncontaminated material* – The term means either of the following:

(1) Fill unaffected by a release of a regulated substance or,

(2) Fill affected by release of a regulated substance, if the concentrations of regulated substances in the fill do not exceed the clean fill concentration limits, as the term is defined in this policy. Analysis should be carried out for only those regulated substances that are suspected to be present due to a release.

The term does not include fill that has been blended, mixed or treated with the purpose of meeting the definition of "uncontaminated material."

Used asphalt **–** Pieces of bitumen and inorganic materials from the demolition of bituminous pavement. The term does not include "reclaimed asphalt pavement," as the term is defined by this policy.

TECHNICAL GUIDANCE:

A. Purpose and Applicability

Fill is used in construction or earthmoving projects across the Commonwealth to level an area or bring an area to grade. These projects may involve using fill as a subbase or to fill in low-lying areas. The manner in which fill may be used depends on whether the fill is clean fill or regulated fill. This policy provides procedures for determining whether fill is clean fill or regulated fill and describes how each category may be managed after a fill determination has been performed.

This policy does not apply to the following activities:

- Mine land reclamation activities subject to a permit.
- Management of waste from land clearing, grubbing and excavation, including trees, brush, stumps and vegetative material.[5]
- Movement or use of fill within a project area or right-of-way of a project.
- Use of reclaimed asphalt pavement in accordance with DEP's industry-wide coproduct determination.
- The use of clean fill or regulated fill prior to January 1, 2020, unless the fill is moved to another receiving site, project area or off the project right-of-way after January 1, 2020.

In general, fill that is demonstrated to be clean fill can be used in an unrestricted manner, provided it is not placed in waters of the Commonwealth; it is used in compliance with 25 Pa. Code, Chapters 102 and 105 (relating to erosion and sediment control; and dam safety and waterway management); and it is managed in accordance with Section D of this policy. Persons using fill must also comply with the fugitive emissions regulations under 25 Pa. Code, Chapter 123 (relating to standards for contaminants) issued under the Air Pollution Control Act, 35 P.S. § 4001, and shall comply with all the applicable provisions of 25 Pa. Code §§ 123.1 and 123.2 (relating to prohibition of certain fugitive emissions and fugitive particulate matter). Depending on the manner in which it is generated, clean fill may be a "waste," as that term is defined in the municipal or residual waste regulations, 25 Pa. Code § 271.1 and § 287.1, respectively, whichever is applicable.

This policy does not apply to fill that has been determined to be clean or regulated fill prior to the implementation of revised CFCLs or RFCLs, unless the fill is moved to a new receiving site or off the project area or project right-of-way after the effective date of the revised CFCLs or RFCLs.

Fill that is demonstrated to be regulated fill can be used by persons who have applied for and obtained coverage under the Department's General Permit No. WMGR096, Beneficial Use of

[5] In accordance with 25 Pa. Code § 271.101(b)(4), a person managing waste from land clearing, grubbing and excavation, including trees, brush, stumps and vegetative material, shall implement best management practices developed by the Department. Refer to Document No. 254-5400-001 - *Best Management Practices for the Management of Waste From Land Clearing, Grubbing, and Excavation (LCGE)*.

Regulated Fill. Coverage under General Permit No. WMGR096 is not required in the following instances:

- Remediation activities undertaken entirely on an Act 2 site, pursuant to the requirements of § 902 of Act 2.

- When fill from an Act 2 site is used as construction material at a receiving site that is being remediated to attain an Act 2 standard, provided the procedural and substantive requirements of Act 2 and the conditions specified in Section C.2.a. and b. of this policy are satisfied.

- Use of the regulated fill is limited to the excavation, movement or use of the regulated fill within a project area or right-of-way of a project.

Regulated fill is a "waste," as that term is defined in the municipal or residual waste regulations, 25 Pa. Code § 271.1 and § 287.1, respectively.

B. Procedure for Performing a Fill Determination

Prior to the movement of fill to a receiving site, either the person proposing to provide the fill from a donor site or the person proposing to receive the fill determines whether the fill is clean fill or regulated fill pursuant to this policy. Use the following steps to make that determination:

1. Determine Eligibility: A material is eligible for management as clean or regulated fill under this policy if it satisfies the following criteria:

    a. The material is "fill," as the term is defined in this policy. If the fill under consideration contains acid-producing rock, it is specifically excluded from the definition of fill. Appendix B contains information relevant to identifying acid-producing rock.

    b. The fill does not contain regulated substances that were intentionally released.

    c. The fill has not been blended, mixed or treated with the purpose of meeting the definition, or applicable numeric limits, of "uncontaminated material," "clean fill" or "regulated fill."

    d. The fill does not exhibit a characteristic of toxicity, as determined by 40 CFR § 261.24 (relating to toxicity characteristic). The toxicity characteristic is of concern only when environmental due diligence indicates that the fill being considered for use may have been affected by a release of a regulated substance that is included in Table 1 in 40 CFR § 261.24. If the total concentration of the substance exceeds the limit for the substance in Table 1 of 40 CFR § 261.24 by a factor of 20 or more, the issue regarding potential toxicity should be addressed either by performing the Toxic Characteristic Leaching Procedure (TCLP), in accordance with Method 1311, found in the most recent version of EPA's publication, *Test Methods for Evaluating Solid Waste, Physical/Chemical Methods*, also known as SW–846, or providing additional description of the fill, indicating that the substance is bound in the matrix and not leaching.

e. PCB-containing Fill: If the environmental due diligence indicates that the fill may have been subject to a release of PCBs, test it for the presence of PCBs. Fill containing a concentration of total PCBs greater than 2 ppm may be subject to regulation under the Toxic Substances Control Act (TSCA), 15 U.S.C. §§ 2601 *et seq.*, and 40 CFR Part 761, which is administered and implemented by the EPA. EPA's TSCA requirements are independent of any use of fill that is otherwise in accordance with the Department's policy and regulations. An applicant should be aware that its characterization and handling of any soils through the guidance of the Management of Fill policy does not necessarily satisfy a potential EPA TSCA inquiry, and that an applicant may need a separate approval from EPA should EPA require it. For all such material, DEP recommends that you contact the PCB Coordinator for EPA Region 3 by email at R3_PCB_Coor@epa.gov to determine whether PCB-containing fill may be used and to obtain information relating to the associated EPA procedures for collecting and analyzing samples.

2. Perform Environmental Due Diligence: Once determined that the fill is eligible for use under this policy, evaluate the fill to determine whether it has been affected by a release of a regulated substance by performing "environmental due diligence," as the term is defined in this policy. Except for historic fill, analytical testing of the fill is not necessary unless environmental due diligence indicates that the fill may have been affected by a release of a regulated substance. However, a person performing a fill determination may choose to perform analytical testing in lieu of conducting a review of ownership and historic property use to satisfy the minimum condition for performing environmental due diligence.

The use of historic fill as clean fill under this policy is limited to historic fill that is a conglomeration of soil, residuals and fill. Historic fill that is comprised primarily of residuals does not represent a conglomeration of soil, residuals, and fill and therefore, cannot be used as clean fill. Pockets of residuals, such as ash or slag, should be removed and managed separately from other historic fill prior to making a determination that the historic fill can be used as clean fill. Perform analytical testing to demonstrate that the historic fill meets the definition of uncontaminated material. To qualify for use as clean fill, historic fill should be tested for the parameters included in Table 1, below, as well as any additional parameters that are suspected based on historic property use or review of records. The placement of historic fill as clean fill may not contaminate groundwater. For regulated substances detected in the historic fill, the value obtained using the Synthetic Precipitation Leaching Procedure, (SPLP, SW-846, Method 1312) may not exceed the numeric value as identified in Table 1 [MSCs for Organic Regulated Substances in Groundwater] and Table 2 [MSCs for Inorganic Regulated Substances in Groundwater] of Appendix A in 25 Pa. Code, Chapter 250.

a. If due diligence shows no evidence that the fill may have been affected by a release of a regulated substance, the fill may be managed as clean fill in accordance with the Section D of this policy (relating to management of clean fill) unless during movement, transport or placement there are observable indications (such as appearance or odors) which indicate evidence of a release of a regulated substance.

b. If due diligence shows evidence that the fill may have been affected by a release of a regulated substance, test the fill to determine if it is clean fill or regulated fill. Perform the testing in accordance with Appendix A of this policy. Analysis should be carried out for only those regulated substances that are suspected to be present due to a release or based upon historic use of the donor site.

i. Except as provided elsewhere in this policy, if testing reveals that the fill contains regulated substances at concentrations that are below the CFCLs, the fill may be managed as clean fill in accordance with Section D of this policy (relating to management of clean fill). A person may not blend, mix or treat fill that would otherwise fail to meet the CFCLs with the purpose of meeting the definition of uncontaminated material or clean fill. For the purposes of completing Form FP-001 for the certification of clean fill, the CFCLs in effect on the date of submission should be used to evaluate whether the fill qualifies for use as clean fill.

ii. Except as provided elsewhere in this policy, if testing reveals that the fill contains regulated substances at concentrations that exceed the CFCLs but are at or below the RFCLs, the fill may be managed as regulated fill only if coverage under General Permit No. WMGR096 is obtained. A person may not blend, mix or treat fill that would otherwise fail to meet the RFCLs with the purpose of meeting the definition of regulated fill. Manage regulated fill in accordance with the Section C of this policy (relating to management of regulated fill).

iii. Except as provided elsewhere in this policy, if testing reveals that the fill contains regulated substances at concentrations that exceed the RFCLs, the fill may not be managed as clean fill or regulated fill. Fill exceeding the RFCLs may require disposal in accordance with the hazardous, municipal or residual waste regulations, 25 Pa. Code, Articles VII, VIII or IX, respectively, whichever is applicable.

TABLE 1: Screening Parameters for Historic Fill

Regulated Substance	CASRN	Regulated Substance	CASRN	Regulated Substance	CASRN
Aldrin	309-00-2	PCB-1254 (Aroclor)	11097-69-1	Copper	7440-50-8

C. Management of Regulated Fill

Regulated fill must be managed in accordance with the Department's municipal or residual waste regulations, 25 Pa. Code § 271.2 and § 287.2, respectively, whichever is applicable, and may be beneficially used in accordance with General Permit No. WMGR096.

Coverage under General Permit No. WMGR096 is not required in the following instances:

1. Remediation activities undertaken entirely on an Act 2 site, pursuant to the requirements of Section 902 of Act 2.

2. When fill from an Act 2 site is used as construction material at a receiving site that is being remediated to attain an Act 2 standard, provided the procedural and substantive requirements of Act 2 and the following are satisfied:

    a. Regulated substances contained in the fill are incorporated into the notice of intent to remediate and the final report for the remediation taking place at the receiving site.

    b. Movement of fill between Act 2 sites is documented in the final reports for both the donor site and receiving site.

    c. Except as provided elsewhere in this policy, placement of the fill does not and will not cause the receiving site undergoing remediation to exceed the selected Act 2 standard.

3. Use of the regulated fill is limited to the excavation, movement or use of the regulated fill within a project area or right-of-way of a project.

A person or municipality interested in obtaining coverage under General Permit No. WMGR096 must apply to the Department in accordance with the application instructions provided in the permit. The terms and conditions of General Permit No. WMGR096 are available on the Department's website.

D. Management of Clean Fill

Pursuant to 25 Pa. Code § 271.101(b)(3) and § 287.101(b)(6), use of clean fill does not require a permit under the SWMA or the municipal or residual waste regulations. Clean fill may be used in accordance with all applicable requirements governing the placement or use of clean fill,

including 25 Pa. Code Chapter 102 (relating to erosion and sediment control) and 25 Pa. Code Chapter 105 (relating to dam safety and waterway management). Persons using fill must also comply with the fugitive emissions regulations under 25 Pa. Code, Chapter 123 (relating to standards for contaminants) issued under the Air Pollution Control Act, 35 P.S. § 4001, and shall comply with all the applicable provisions of 25 Pa. Code §§ 123.1 and 123.2 (relating to prohibition of certain fugitive emissions and fugitive particulate matter). The use of clean fill may be regulated under other environmental laws and regulations.

If the uncontaminated brick, block or concrete from a construction or demolition activity is intended for use as clean fill, best management practices (BMPs) should be followed prior to demolition activities to remove from a building or structure all materials that do not meet the definition of clean fill, such as materials or surfaces covered with lead-based paint, friable asbestos, and hazardous materials such as mercury switches, PCB ballasts, tritium-containing exit signs, and fluorescent light bulbs.

Clean fill may not contain any free liquids based on visual inspection and cannot create a public nuisance (such as an objectionable odor) to users of the receiving site or adjacent properties.

If any person wants to use clean fill under this policy, complete Form FP-001, Certification of Clean Fill, and submit it to DEP electronically on the DEP website at https://www.dep.pa.gov/Business/Land/Waste/SolidWaste/Residual/Pages/default.aspx. Complete and submit the FP-001 prior to movement of clean fill to the receiving site. Complete and submit FP-001 regardless of whether sampling and analysis are performed as part of environmental due diligence.

If the donor site has undergone or is undergoing cleanup or remediation under a local, state or federal regulatory program that requires site characterization, or if the fill proposed to be managed as clean fill has otherwise been subject to analytical testing or other procedures identified in the definition of "environmental due diligence," attach the following to Form FP-001:

- Copies of the sampling plan developed for the fill,
- All laboratory reports,
- Documentation and data associated with a background determination and equivalent site evaluation conducted as part of the fill determination, including the identification and location of point sources, the proximity of identified point sources to the background reference area, identification of areas of imported fill other than imported clean fill, etc.

If a person receives fill from multiple donor sites, a separate Form FP-001 is necessary for each donor site. DEP will accept the completed FP-001 electronically via a link on the DEP website.

If a background demonstration is made, as described in Appendix A of this policy, use the FP-001 to include documentation of the background demonstration along with documentation demonstrating that an equivalent site evaluation has been performed and the provisions of Appendix A have been satisfied.

Both the donor site and the receiving site are responsible for maintaining copies of the completed Form FP-001 for a period of five (5) years. Copies of the form and all supporting documentation, including analytical test reports, should be made available and provided to DEP upon request.

Appendix A
Sample Collection and Analytical Testing Protocol for Performing Environmental Due Diligence

Prior to movement of fill to a receiving site, use Sections B-D of the Management of Fill policy to make a fill determination. Analytical testing of the fill is not necessary unless environmental due diligence indicates a release of a regulated substance. This Appendix provides guidelines for using analytical testing as part of the environmental due diligence.

A. Sampling Plan Development

The first step in a chemical evaluation of fill is to develop a plan for sampling. To use analytical testing as part of the environmental due diligence, develop and implement a scientifically credible sampling plan in accordance with the most recent version of the EPA's publication, *Test Methods for Evaluating Solid Waste, Physical/Chemical Methods,* also known and hereinafter referred to as SW-846, and the *RCRA Waste Sampling Draft Technical Guidance, EPA530-D-02-002*. Chapter 9 of SW-846 describes procedures for developing a sampling plan and the statistical treatment of data. Where there is disagreement between the procedures outlined in this Appendix and the referenced EPA documents, follow the procedures contained in this Appendix.

Employ a systematic planning process, such as the Data Quality Objectives Process identified in the *RCRA Waste Sampling Draft Technical Guidance*, to set objectives for the type, quantity and quality of data needed to demonstrate with a known level of assurance that the applicable standards for clean fill or regulated fill are achieved. The level of complexity and detail needed in the sampling plan are directly related to the size, scope and level of complexity of the donor site.

The following are the minimum scientific objectives of a sampling plan developed under this policy:

- Identify and quantify known or suspected contaminants in the fill.
- Collect samples that will allow measurements of the chemical properties of the fill that are both accurate and precise.
- Collect representative samples, which for the purposes of implementing this policy are samples exhibiting typical properties of the whole volume of fill.
- Collect enough samples, and in no case less than eight discrete samples or two composite samples, to sufficiently represent the variability of the fill.
- Obtain a statistically valid and reliable estimate of the fill's chemical properties.

Characterize the fill both horizontally and vertically to represent the entire volume of fill to be transported off the donor site and used at a receiving site. A thorough characterization will provide the following information:

- Identity of regulated substances associated with a release that are present in the fill, the concentration of each identified regulated substance, and the spatial variation in concentration of each regulated substance both horizontally and vertically.

- The physical characteristics of the fill in which the regulated substances associated with a release are present. Examples of these include the fill type (such as soil, rock, dredge), texture, dry bulk density, permeability, organic carbon content, porosity, and moisture content. Include documentation of physical characteristics and any significant variability over the donor site.

In the sampling plan include a summary of existing information about the donor site, including any previously performed sampling or analysis information, preliminary estimates of summary statistics such as the mean and standard deviation, process descriptions and materials used, spatial boundaries of the donor site to be managed under this policy, information about what is known or suspected at the donor site, releases, and release mechanisms. Document this information by written descriptions of site conditions supported by maps, cross-sections, site diagrams, or other descriptive, graphical, or tabular illustrations necessary to characterize the site conditions.

Sampling units for fill managed under this policy should represent the total volume of fill being characterized pursuant to Sections B and C of this Appendix. Sampling plans may include a combination of probability sampling and authoritative sampling designs depending on conditions at the donor site. Probability sampling should be used to characterize the fill as a whole. Some sites may require additional, more focused sampling, such as authoritative sampling, to evaluate problem areas, such as localized areas that are suspected to contain the highest levels of regulated substances, or "hot spots," or areas that may require further evaluation. For example, areas that housed an underground storage tank or experienced a release of regulated substances should be sampled authoritatively and more frequently than other areas of the donor site. The remaining area of the donor site should be sampled using probability sampling, in which all parts of the fill being characterized have a known probability of being included in the characterization. Samples collected to delineate a "hot spot" are typically in addition to those collected for the overall site characterization.

B. Sampling Procedures for Fill Stored in Piles

There are several variables involved in the sampling of fill stored in piles, including the size and shape of the pile, compactness of the fill, and physical properties of the fill. The size and shape of the pile should be used to calculate volume and plan for the correct number of samples to be taken. Simple random sampling or stratified random sampling should be used to obtain representative samples from a fill pile, in accordance with SW-846 and Sections 5.2.1 – 5.2.2, and 5.3 of the *RCRA Waste Sampling Draft Technical Guidance, EPA530-D-02-002*. A method of random sampling, such as simple random or stratified random sampling should be used unless one of the following conditions exists:

- There are known distinct strata.

- An objective of the sampling is to prove or disprove that there are distinct strata.

- The number of samples is limited, and an objective of the sampling is to statistically minimize the size of a "hot spot" that might not get sampled.

Stratified random sampling can be employed only if all points within the pile can be accessed. In such cases, the pile should be divided into a three-dimensional grid system. The grid cubes should be numbered, and the grid cubes to be sampled should be chosen by random number tables or generators.

Generally, stainless-steel shovels, trowels, or scoops should be used to clear away surface material before samples are collected. Depth samples may be collected using a decontaminated auger. For a sample core, thin-wall tube samplers or grain samplers may be used. Near surfaces, samples can be collected with a clean, stainless-steel spoon or trowel. All samples collected, except those for VOCs analysis, should be placed into a Teflon-lined or stainless-steel pail and mixed thoroughly before transfer to the appropriate sample container. Since volatilization of VOCs can occur rapidly once the matrix is disturbed, grab samples are necessary for VOCs analysis. Grab samples should be handled as intact cores and transferred immediately to the container that will be used for analysis. Refer to SW-846, Method 5035, for container and preservation details specific to samples for VOCs analysis.

The sampling and subsequent analysis of fill stored in piles may be performed by collecting composite or discrete samples.

1. Procedure for Using Composite Samples:

    a. Do not use composite sampling if the integrity of the individual sample changes because of the physical mixing of discrete samples.

    b. For up to 125 cubic yards of fill, collect and handle eight discrete samples (plus two grab samples for VOCs) as follows:

        i. Prior to compositing, field screen the eight discrete samples to identify the two that are most likely to contain the highest concentrations of VOCs.

        ii. In accordance with SW-846, Method 5035, collect grab samples for VOC analysis from the two points identified by the field screening described above.

        iii. For all other substances, combine the eight discrete samples collected into two composite samples comprised of four discrete samples each. Perform the analysis on the two composite samples in accordance with SW-846.

c. For greater than 125 cubic yards and up to and including 3,000 cubic yards, collect and handle 12 discrete samples (plus three grab samples for VOCs) as follows:

i. Prior to compositing, field screen the 12 discrete samples to identify the three samples that are most likely to contain the highest concentrations of VOCs.

ii. In accordance with SW-846, Method 5035, collect grab samples for VOC analysis from the same sampling points as the three discrete samples identified by field screening.

iii. For all other substances, combine the 12 discrete samples collected into three composite samples comprised of four discrete samples each. Perform the analysis on the three composite samples in accordance with SW-846.

d. For each additional 1,000 cubic yards of fill or part thereof over the initial 3,000 cubic yards, collect four additional discrete samples (plus one grab sample for VOCs). Composite and analyze the four discrete samples in accordance with SW-846.

2. Procedure for Using Discrete Samples:

a. For up to 125 cubic yards of fill, collect and analyze a minimum of eight discrete samples (plus two grab samples for VOCs). For volumes of fill greater than 125 cubic yards and up to and including 3,000 cubic yards, collect and analyze a minimum of 12 discrete samples (plus three grab samples for VOCs). For each additional 1,000 cubic yards of fill or part thereof over the initial 3,000 cubic yards, collect and analyze a minimum of four additional discrete samples (plus one grab sample for VOCs).

b. For VOCs analysis, perform grab sampling as described in subsection B.1 of this Appendix.

C. Sampling Procedures for In-situ Fill

For the purposes of this policy, “in-situ fill” refers to fill that is undisturbed in its original location at the donor site or fill that has previously been used as clean or regulated fill and will be subsequently excavated and moved to a receiving site. If conducting sampling on in-situ fill to evaluate whether that fill can be managed as clean or regulated fill, characterize both the vertical and horizontal extent of the fill to be transported and used at a receiving site. Where multiple zones of contamination are possible due to site-specific conditions, including separate and discrete releases or the manner in which fill was originally placed, the characterization and demonstration that the fill meets the CFCLs or RFCLs apply individually to the separate zones.

For in-situ sampling where the purpose of the sampling is to characterize a specific release at the donor site, discrete samples collected using a focused sampling technique, such as authoritative sampling, must be used for analysis. These areas may be:

- Localized areas that are known to contain levels of regulated substances that exceed the CFCLs or RFCLs, whichever is applicable, based on analytical results, or

- Localized areas suspected to contain levels of regulated substances that exceed the CFCLs or RFCLs from a specific release, whichever is applicable, based on the historic use of the site.

Once the specific release at the donor site has been characterized, composite samples may be used to confirm that the remaining fill to be excavated and transported to a receiving site and used as clean or regulated fill meets the CFCLs or RFCLs, respectively.

To characterize the remaining area, the area should be sampled using a method of random sampling, such as simple random or stratified random sampling. Composite samples can then be used to verify that the fill intended for excavation and transportation meet the CFCLs or RFCLs, whichever is applicable. When composite samples are utilized for in-situ samples, the sampling plan must demonstrate that localized areas that are known to contain regulated substances exceeding the CFCLs or RFCLs, whichever is applicable, are not included in the portion of the site evaluated using composite samples.

Apart from known hot spots, which may require further sampling and analysis, as discussed above, the donor site should be divided into a three-dimensional grid. Where possible, each grid unit should be of similar size and shape and be comprised of equal volumes of fill. A method of random sampling, such as simple random or stratified random sampling, should be chosen based on knowledge of the donor site as set forth in SW-846 or the *RCRA Waste Sampling Draft Technical Guidance, EPA530-D-02-002*.

The number of sample points is determined by the volume of fill being characterized. Sampling frequency should account for the depth of donor fill to be removed. If an area of donor fill will be excavated to more than one depth (for example, three feet in one part and six feet in another part), then the samples should be distributed accordingly at multiple depths to be representative of the full depth of each cut. Determine the minimum number of samples using the procedure outlined in subsection B.2 of this Appendix. Additional sampling may be necessary based on site-specific conditions.

D. Evaluation of Data

Evaluate sample data generated in accordance with Sections B and C of this Appendix in accordance with the following:

1. For a composite sample collected in accordance with subsection B.1, the measured numeric value for a parameter may not exceed the CFCL for that parameter for the fill to be managed as clean fill, or the RFCL for that parameter for the fill to be managed as regulated fill.

2. For a grab sample collected for VOC analysis in accordance with the above sections, the measured numeric value for a parameter may not exceed the CFCL for that parameter for the fill to be managed as clean fill, or the RFCL for that parameter for the fill to be managed as regulated fill.

3. For discrete samples collected in accordance with subsection B.2, the measured numeric values for a substance in 75% of the discrete samples may not exceed the CFCL for that parameter for the fill to be managed as clean fill, or the RFCL for that parameter for the fill to be managed as regulated fill. For persons using the discrete sampling method, no single sample may show regulated substances at a concentration that is more than twice the CFCL or RFCL, whichever is applicable, for any parameter.

E. Alternate Evaluation of Data

In lieu of Section D of this Appendix, a person may use the 95% Upper Confidence Limit (UCL) of the arithmetic mean to determine whether the fill meets the CFCL or RFCL, whichever is appropriate, for a parameter. The calculated 95% UCL of the arithmetic mean should be below the appropriate CFCL or RFCL for that parameter. Persons intending to use this method for the treatment of data should determine a minimum number of samples in accordance with SW-846 and the *RCRA Waste Sampling Draft Technical Guidance, EPA530-D-02-002*. The application of the 95% UCL of the arithmetic mean should comply with the following performance standards:

1. The null hypotheses (Ho) is that the true arithmetic average concentration is at or above the CFCL or RFCL for that parameter, whichever is appropriate, and the alternative hypothesis (Ha) is that the true arithmetic average concentration is below the CFCL or RFCL for that parameter, whichever is appropriate.

2. Meet the underlying assumptions of the statistical method, such as data distribution.

3. Compositing cannot be used for VOCs.

4. The censoring level for each non-detect is the assigned value randomly generated that is between zero and the limit related to the practical quantitation limit (PQL).

5. Tests should account for spatial variability, unless otherwise approved by the Department.

6. Statistical testing should be done individually for each parameter for which a single sample result or multiple results exceed(s) a limit.

7. Where a fill has distinct physical, chemical or biological characteristics, or originates from different areas, do the statistical testing separately.

8. Document the following information:

    a. A description of the original areas of the fill and physical, chemical and biological characteristics of the fill.

b. A description of the underlying assumptions of the statistical method.

c. Documentation showing that the sample data set meets the underlying assumptions of the statistical method.

d. Documentation of input and output data for the statistical test, presented in tables or figures, or both, as appropriate.

e. An interpretation and conclusion of the statistical test.

F. Use of the Synthetic Precipitation Leaching Procedure (SPLP, SW-846 Method 1312) to Establish an Alternative Soil-to-Groundwater Value

Fill may be analyzed using SPLP to provide an alternative soil-to-groundwater value for use in making a fill determination. The value obtained using the SPLP represents a concentration of a regulated substance in the fill that does not produce leachate in which the concentration of the regulated substance exceeds the applicable groundwater MSC identified in Table 1 [MSCs for Organic Regulated Substances in Groundwater] or 2 [MSCs for Inorganic Regulated Substances in Groundwater] of Appendix A in 25 Pa. Code, Chapter 250. For both clean and regulated fill, the groundwater MSC for used aquifers with TDS <2,500 mg/L should be used to compare the SPLP result to Tables 1 or 2. For clean fill, use the groundwater MSC for residential use ("R") for comparison. For regulated fill, use the groundwater MSC for non-residential use ("NR") for comparison. If SPLP is used to identify an alternative soil-to-groundwater value, the alternative value is only applicable to the fill that was tested using SPLP.

Use the following procedure to determine an alternative soil-to-groundwater value based upon the SPLP:

1. During characterization of the donor site, obtain a minimum of ten samples from the proposed fill. For volumes of fill less than 125 cubic yards, collection of a minimum of eight samples is acceptable. Submit the four samples with the highest total concentration of the regulated substance for SPLP analysis. Samples obtained will be representative of the soil type and horizon impacted by the release of the regulated substance.

2. Determine the lowest total concentration (TC) that generates a failing SPLP result. The alternative soil-to-groundwater value will be the next lowest TC.

3. If all samples result in a passing SPLP level, the alternative soil-to-groundwater value will be the TC corresponding to the highest SPLP result. Additional samples may be collected.

4. If none of the samples generates a passing SPLP, additional samples may be collected and concurrent TC/SPLP analyses performed to satisfy the above conditions for establishing an alternative soil-to-groundwater value.

5. The alternative soil-to-groundwater value is then compared to the direct contact residential value for clean fill or the direct contact non-residential value for regulated fill

found in Chapter 250, Appendix A, Tables 3[6] or 4[7]. The lower of the compared values is the applicable numeric limit.

G. Performing a Background Demonstration and Equivalent Site Evaluation

A background demonstration may be utilized for both clean fill and regulated fill determinations. For clean fill determinations, use the CFCLs. For regulated fill, use the RFCLs. If fill from the donor site contains regulated substances at concentrations exceeding the CFCL or RFCL, whichever is appropriate, for that parameter, a demonstration may be made to show that the exceedance is due to background at the donor site. If a successful background demonstration is made, perform an equivalent site evaluation prior to movement of fill to a receiving site. The equivalent site evaluation ensures that no new regulated substance is placed on the receiving site other than a regulated substance already determined to be present and that the concentration(s) of regulated substance(s) in the donor fill has been compared to the concentration(s) of the same regulated substance(s) at the receiving site in accordance with subparagraphs G.3.b.i-ii. of this Appendix. Regulated substances detected in the donor fill that are below the CFCL or RFCL, whichever is appropriate, for that parameter, do not require a background demonstration or an equivalent site evaluation.

Generally, only naturally occurring metals, lead and some ubiquitous organics, such as polynuclear aromatic hydrocarbons (PAHs), from widespread atmospheric deposition, are eligible for a background demonstration. When data or other information indicates that a regulated substance has migrated onto the donor site from the release of a regulated substance at another site, the regulated substance is not due to background of that substance at the donor site. Pathways for the migration of a regulated substance due to an offsite release include surface runoff from specific sources (such as runoff from parking lots and storage facilities where spills have occurred); spills at railroad facilities and in railroad rights-of-way; and air deposition of regulated substances from specific sources.

Previously collected background data published by an accredited source with appropriate peer review may be considered, provided the information is sufficiently focused and contains the level of detail on the area used to determine background necessary to legitimately compare it to the donor site. The description of the sampling and analysis performed should be detailed enough to provide statistical validity.

Use the following guidelines when performing a background demonstration under this policy:

1. Select a Background Reference Area:

   The first step in making a demonstration that the presence of a regulated substance is due to background at the donor site and is not due to a release is to select a background reference area, as the term is defined in this policy, to collect samples for the purpose of establishing background at the donor site. Samples may be collected from the background reference area to demonstrate that an exceedance of a CFCL or RFCL, as appropriate, can be attributed to background, as the term is defined in this policy. Background reference areas should not include areas affected by a known or suspected

[6] Direct contact numeric values for soils at residential properties
[7] Direct contact numeric values for soils at non-residential properties

release of a regulated substance, including areas impacted by road runoff, areas near railroads affected by engine exhaust contaminants, and areas near buildings contaminated by paint chips. In urban areas, background reference areas may include areas where widespread, ubiquitous contamination is present that cannot be traced to a specific source.

Background reference areas should be as similar as possible to the donor site. Every attempt should be made to reduce the factors that are different between the background reference area and the donor site. This does not mean that a sample collected at a location that is a considerable distance from an area known or suspected to have been affected by a release of a regulated substance is unacceptable merely because the known or suspected regulated substance is detected in the sample. The presence of regulated substance outside of the area known or suspected to have been affected by a release may indicate that the presence of the regulated substance is truly ubiquitous, widespread and incapable of being traced to a specific source. In this case, the regulated substance may be part of the background at the donor site.

A background reference area, as the term is defined in this policy, should be selected for use in the background demonstration.

2. Sampling, Analysis and Evaluation of Data:

Establish background by a sampling methodology that is statistically valid and consistent with the methodology used to perform the fill determination. Use the same analysis methods for the background samples that were used for performing the fill determination.

Compare the analytical results of the background samples with the results obtained from the fill determination. Use the following statistical methods for the comparison:

a. Demonstrate that the highest measurement from the donor site is not greater than the highest measurement from the background reference area. The Department may accept insignificant variances in numbers. The minimum number of samples to be collected is 10 from the background reference area and 10 from each donor site. Analysis should be carried out on discrete samples.

b. The Department may accept another appropriate statistical method if it meets the conditions below.

    i. For nonparametric and parametric methods, the false-positive rate for a set of data applied to a statistical test may not be greater than 0.05. The minimum number of samples to be collected is 10 from the background reference area and 10 from each donor site.

    ii. For parametric methods, the censoring level for each non-detect (ND) should be the assigned value randomly generated that is between zero and the limit related to the PQL.

3. Equivalent Site Evaluation:

The equivalent site evaluation ensures that no new regulated substance is placed on the receiving site other than a regulated substance that is already determined to be present and that the concentration(s) of regulated substance(s) in the donor fill has been compared to the concentration(s) of the same regulated substance(s) at the receiving site in accordance with subparagraphs G.3.b.i-ii. of this Appendix. Regulated substances detected in the donor fill that are below the CFCLs or RFCLs, as appropriate do not need to be included in the equivalent site evaluation. Perform the equivalent site evaluation prior to the movement of fill to a receiving site. Include documentation in the FP-001 demonstrating that the equivalent site evaluation has been performed and is satisfied in accordance with this section.

a. Develop a Plan for Sampling the Receiving Site.

Make a background determination on the receiving site to determine whether the same regulated substances present in the donor fill due to background are also present at the receiving site, and if so, determine the concentrations of the identified regulated substances. Development of a sampling plan in accordance with Section A of this Appendix is necessary to characterize the receiving site.

In the sampling plan include a summary of existing information about the receiving site, including any previously performed sampling or analysis information, process descriptions and materials used, spatial boundaries of the receiving site, information about what is known or suspected at the receiving site, releases, and release mechanisms. Document this information by written descriptions of site conditions and supported by maps, cross-sections, site diagrams, or other descriptive, graphical, or tabular illustrations necessary to characterize the site conditions.

The receiving site should be sampled using probability sampling, in which all parts of the site being characterized have a known probability of being included in the characterization, except for areas of the receiving site that are known to be or suspected of being affected by a release of a regulated substance, including areas impacted by road runoff, areas near railroads affected by engine exhaust contaminants, and areas near buildings contaminated by paint chips, unless the entire receiving site is part of a larger urban area where ubiquitous, widespread contamination is present that is incapable of being traced to a specific source.

Select the area of the receiving site used for the equivalent site evaluation in accordance with the following:

i. The area sampled is unaffected by a release of a regulated substance.

ii. The area sampled should be at a depth comparable to the area where donor fill is to be placed on the receiving site.

iii. The concentration of regulated substances in the area sampled is attributable to the parent material from which the soil was derived and the

natural processes which produce soil; or the concentrations of regulated substances resulted from an atmospheric deposition, as the term is described in the definition of "background reference area," but are not attributable to a specific point source or release of a regulate substance.

b. Sampling, Analysis and Evaluation of Data.

Establish the background by a sampling methodology that is statistically valid and consistent with the methodology used to perform the fill determination. Use the same analysis methods for background samples that were used for performing the fill determination.

Compare the analytical results of background samples for the receiving site with the results obtained from the donor fill. Use one of the following statistical methods for comparison:

i. Demonstrate that the highest measurement from the donor site is not greater than the highest measurement from the receiving site. The Department may accept insignificant variances in numbers. The minimum number of samples to be collected is 10 from the receiving site and 10 from each donor site.

ii. The Department may accept another appropriate statistical method if it meets the conditions below.

(A) For nonparametric and parametric methods, the false-positive rate for a set of data applied to a statistical test may not be greater than 0.05. The minimum number of samples to be collected is 10 from the receiving site and 10 from each donor site.

(B) For parametric methods, the censoring level for each non-detect (ND) should be the assigned value randomly generated that is between zero and the limit related to the PQL.

Appendix B
Recognition and Identification of Acid-Producing Rock

Pennsylvania's municipal and residual waste regulations define clean fill, in part, as inert solid material. Acid-producing rock reacts when exposed to air or water and therefore does not meet the regulatory definition of clean fill. In addition to presenting abrupt and adverse environmental concerns, exposed acid-producing rock can also have long-term damaging effects on highways and highway structures, including corrosion of concrete and steel structures; destabilization of cut slopes and fill slopes; ground heaving of structures and pavements; toxicity to roadside vegetation and aquatic life; and degradation of drinking water supplies.

Determining whether or not fill contains acid-producing rock begins with determining the presence of or likelihood of encountering acid-bearing rock (ABR), which is widespread in Pennsylvania. The primary source of acidity in Pennsylvania sedimentary rocks is sulfide minerals. Although there are many minerals that contain sulfur, those containing pyrite, or ferrous disulfide, are the major contributors to the release of acid. While pyrite minerals are not always large enough to be visible to the unaided eye, larger crystals have a yellowish, metallic appearance. Deposits containing pyrite concentrations greater than 0.5% have the potential to be significant sources of acid. Various other forms of sulfide minerals are of lesser concern due to their chemical stability, and include chalcopyrite (CuFeS2), galena (PbS) and sphalerite (ZnS), but can be problematic when present with pyrite.

Although there are more than 200 common minerals that contain sulfur, only those classified as iron sulfide are of potential concern due to the ability of these elements to promote oxidation, hydration and the release of acid. In Pennsylvania, there are four potential sulfide deposit types, listed as follows in descending order of pyrite oxidation reactivity:

- Veined Rock Deposits;
- Sedimentary Rock Deposits;
- Mine Spoils; and
- Acid Sulfate Soil Deposits.

Typically, the upper 25- to 35-feet of bedrock does not contain pyrite because pyrite is not stable under atmospheric conditions and will weather away. Therefore, if excavations are shallower than 30 feet, the risk of acid release is generally minimal. This is particularly true if a site is located south of the glacial margin. Within the glaciated regions of Pennsylvania, weathered bedrock may have been removed by glaciers and pyrite may exist closer to the surface. Unconsolidated sediments, such as glacial till, sand, and gravel, are not acid-producing and can be excavated without risk of acidic drainage. With regard to characterization of fill excavated to depths greater than 25 feet, environmental due diligence should include details demonstrating that the fill does not contain acid-producing rock.

The following publicly available resources may also assist in assessing the likelihood of encountering ABR:

- The Pennsylvania Geological Survey's a map of potentially acid bearing rocks (OFMI Report 05-01.1);
- The Pennsylvania Department of Transportation's (PennDOT) Geotechnical Engineering Manual, Publication 293 (4/18) (PUB 293 (4/18)); and
- DEP's Fact Sheet titled, "How to Avoid and Handle Acid-Producing Rock Formations Encountered During Well Site Development" (PA DEP Link)

If ABR is anticipated in the fill based on published information or identified during due diligence, testing should be done to estimate the acid-producing potential. For more information on testing procedures and acid-base accounting procedures, please refer to PennDOT's "Geotechnical Engineering Manual, Publication 293 (4/18) (PUB 293 (4/18))," DEP's "Coal Mine Drainage Prediction and Pollution Prevention in Pennsylvania (Coal Mine Drainage Prediction and Pollution Prevention)" or DEP's "Evaluation of Acid-Base Accounting Using Computer Spreadsheets (Evaluation of Acid-Base Accounting)."

A. Arcadis' July 2021, Remedial Investigation Report and Cleanup Plan

1. Introduction

On behalf of BP Bridesburg, LLC (Bridge), Roux Associates, Inc. (Engineer) has prepared this Soil Management Plan (SMP) for the property located at 4501 Richmond Street in Philadelphia, Pennsylvania (Site) as a construction support document associated with the redevelopment of the Site.[1]

Philadelphia Coke, Co., Inc., (PCC) the prior owner of the Site, previously performed extensive soil remediation at specific Hazardous Waste Management Units as part of Resource Conservative and Recovery Act (RCRA) closure activities. Additional remediation work included the removal and disposal of underground storage tanks (USTs) and associated piping, and bioremediation to address contamination in a former fuel blending area. On December 28, 1994, the United States Environmental Protection Agency (USEPA) issued a Certificate of Completion for RCRA. Furthermore, on November 19, 2018, a Notice of Intent to Remediation (NIR) was submitted to the Pennsylvania Department of Environmental Protection (DEP) stating that PCC is seeking a release of liability under the Act 2 Site-Specific Standard. The objective of the Act 2 Site-Specific Standard, and a summary of the previously completed remedial investigation and action activities are documented in Arcadis' July 2021, *Remedial Investigation Report and Cleanup Plan* (provided as **Attachment A**).

The Site is approximately 63 acres in area and is listed in the USEPA Corrective Action Program with EPA ID: PAD000427906. PCC formerly operated at their facility from the mid-1920's through 1989 for manufacturing gas production, metallurgical coke production and fuel oil blending operations. Previous investigation activities completed by PCC determined that Site constituents of concern (COCs) in soil are generally limited to polycyclic aromatic hydrocarbons (PAHs), arsenic, lead and limited polychlorinated biphenyl (PCBs). Visual impacts (e.g., viscous tar, oil-like material, and solidified tar) are limited to the fill layer or the top few feet of the silt and clay layer.

The goal of the SMP is to ensure that all future earth work activities associated with the re-development of the Site are conducted with the ultimate goal for the final development to facilitate a more protective remedy. This SMP has been prepared to provide the selected earth work contractor with direction regarding the management of soils and other environmental issues that result from the presence of any potential contamination that may be encountered during development activities. Specifically, the SMP describes activities to be undertaken during soil cutting and filling activities and describes procedures to be followed in the event that specific unexpected conditions arise.

The best management practices for the anticipated earth work activities are summarized in the following sections. A Site Location Map depicting the Site location and the surrounding area is provided as **Figure 1**.

[1] It is anticipated that future development will consist of two warehouses encompassing a total area of approximately 901,500 square feet.

2. On-Site Soil Management Process

The methods to be implemented whenever soils are being handled at the Site during the re-development phase of work take into account the soil quality at different areas and any restrictions that apply to those areas.[2] Soil/material handling will be managed under three distinct categories: 1.) Non-Restricted Use soils; 2.) Restricted Use soils; and 3.) Unanticipated material. For purposes of on-Site soil/material placement, the Site soils will be divided into two areas: soils from the Non-Restricted Use Area, and soils from the Restricted Use Area. Any unanticipated materials (e.g., USTs,. non-aqueous phase liquids [NAPL], soil deemed insufficient for geotechnical purposes, etc.) identified during the development phase of work will be temporarily staged, characterized and disposed of, or utilized depending on the material and the generated analytical data, as further discussed in Section 2.3.[3] The Non-Restricted Use Area and Restricted Use Area are presented on **Figure 2**.

2.1 Non-Restricted Use Soils

The Non-Restricted Use Area is defined as all areas of the Site with the exception of the Historical Tar/Fill Area, depicted on **Figure 2**; however, USEPA regulated waste may be encountered within the following areas:

- Area 1 – Eastern Part of Former Coal Storage Area
- Area 2 – North/Northwest of Former Tar Storage Area
- Area 3 – South of Former Tar Storage Area
- Area 4 – Former AST Farm East of Former Byproducts Operations

When earthwork is performed within the limits of Area 1 through Area 4, care will be taken to inspect and evaluate the condition of the fill material. If the fill material within Area 1 through Area 4 exhibits any signs of Restricted Use Soils (e.g., through olfactory observation, field screening, laboratory analytical testing, etc.), fill shall be stockpiled for future disposal or utilized within the Restricted Use Area.

As part of future development activities, Bridge plans to excavate soils within this area and relocate to different portions of the Site to achieve the desired grading elevations. As presented on **Figure 3**, approximately 66,000 cubic yards of soil will need to be cut, and approximately 183,000 cubic yards of soil will be used as fill. With the exception of the conditions outlined in the below Restricted Use Soils section, soils within the Non-Restricted Use Area are available to be utilized as fill material throughout the Site.

2.2 Restricted Use Soils

The Restricted Use Area is defined as the Historical Tar/Fill Area, depicted on **Figure 2**. As part of future construction activities, soil encountered within the Restricted Use Area may be moved throughout the Restricted Use Area to allow for redevelopment and to achieve the final desired elevations and grades. During the excavation of soils within the Restricted Use Area, care will be taken to segregate the clean surface materials from the underlying impacted soil to prevent intermingling. In addition, soils excavated from the Restricted Soil Area and have evidence of impact (i.e., staining, NAPL, odor, etc.) or are characterized as hazardous material via laboratory analysis will be stockpiled within a designated area within the limits of the Restricted Soil boundary to avoid mixing with other on-Site materials or imported fill. Erosion and Sediment Control (ESC) plans will include location of the designated soil stockpile area, location of final placement of materials from the Restricted Soils Area and applicable erosion control measures.

All soil and non-soil materials (e.g., riprap, DGA, backfill, etc.) imported to the Site to achieve desired final grades will be reviewed by Bridge and Engineer to ensure compliance with the PADEP's Bureau of Waste

[2] For the purposes of this SMP, excavation is defined as any activity disturbing the underlying material beneath the engineering controls.

[3] As further discussed in Section 2.3, unanticipated material will be temporarily staged, characterized, and disposed of or utilized depending on the material and the generated analytical data.

Management's January 16, 2021, *Management of Fill Policy* (PADEP Fill Policy). This includes, but is not limited to soil, soil like material, backfill, stone, road base, Class B recycled material, gravel, etc. The PADEP Fill Policy describes the type of fill that qualifies as clean fill and outlines the frequency at which imported material will be sampled as well as other requirements. Bridge is currently proposing to raise the grade of the Site with clean fill. If it is determined alternative fill will be used to raise the grade of the Site, an addendum to the SMP will be generated that details the plans for sampling, laboratory analysis, quality control/assurance, health, and safety as well as proper documentation of fill that will be brought on Site. In addition, Bridge understands there are limitations and will adhere to said regulations where regulated fill can be placed as it relates to the 100-year flood plain, surface water and waters of the Commonwealth of Pennsylvania.

2.3 Encountering Unanticipated Material

Although extensive investigation work has been completed at the Site, Engineer has developed an alternative material management approach in the event that any unanticipated material is encountered during development work including but not limited to USTs; and NAPL. Note that if unanticipated material is encountered, it will be considered hazardous waste and will be managed as such until sampling data deems it non-hazardous. The protocols and procedures to manage the unanticipated material are further described below.

2.3.1 Staging and Segregation Protocol

In the event material is encountered that requires off-site disposal, the material will be temporarily placed on plastic sheeting (minimum 12-mil thickness) adjacent to the excavation area and kept covered with appropriately anchored tarps when inactive. If impacted material is selected to be disposed off-site, it will be placed directly within off-site haul vehicles, as practical, to reduce double handling of material. Small quantities of waste, along with drums of used personal protective equipment and similar small debris type items, may be stored in labeled Department of Transportation (DOT) Specification containers before on-Site reuse or off-site disposal. Care will be taken to not contaminate other areas of the Site during the staging and loading process.

2.3.2 Sampling Protocol

Once soils are transported to the staging area, Engineer will coordinate with local PADEP approved disposal facilities to develop the required sampling frequency and analysis protocol to achieve approval for off-site disposal. The sampling plan will include the collection of grab and composite samples and all analyses will be performed using appropriate EPA methods, and within the recommended quality assurance/quality control (QA/QC) parameters. Once a stockpile has been sampled, no additional soil or material will be added to the pile. In addition, soil piles from different portions of the Site or stockpiles with different COCs will not be combined, unless previously authorized by the intended soil disposal facility.

In the event that a UST and associated piping are encountered, the tank and piping will be cleaned, and the generated residual waste will be stockpiled and sampled pursuant to the above-described methods.

2.3.3 Off-Site Transportation and Disposal

The following section of the SMP addresses the off-site transportation and disposal of material that is deemed not suitable for development which includes Site preparation, soil loadout, transport vehicle decontamination and the required truck route. All waste disposal activities will be conducted in accordance with the PADEP Waste Transportation Safety Act.

2.3.3.1 Waste Loadout

Stockpiled materials will be loaded into trucks for transport to the approved soil disposal facility. Conventional equipment, such as front-end loaders and hydraulic excavators, will be used to load the soil piles into the transport vehicles. Transport vehicles will not be loaded in excess of the approved axle rating and care will be taken to prevent the spread of dust and/or contamination of vehicles during load out.

Bridge and Engineer will ensure that the soil trucking company is licensed and permitted in all states through which they will travel with decals/placards appropriate for the waste material removed from the Site. This includes having a PADEP Waste Transporter Authorization issued under Act 90. Bridge and Engineer will ensure that the soil trucking company meets the applicable DOT training requirements, and provides a list of vehicles and DOT approved containers which will be available for use on the project, DOT violation history and a list of other projects similar in magnitude to this project with contact names and telephone numbers.

2.3.3.2 Transportation Vehicle Inspection and Decontamination

Transport vehicles shall be inspected by trucking company personnel upon the completion of loadout activities. Tailgate locks and cover tarps will be inspected to ensure that they are secure and will prevent the release of soil, dust or materials during transport. Truck tires and undercarriage members will be inspected for visible accumulations of soil and will be cleaned as necessary.

Transport vehicles that were exposed to visible accumulations of soil on tires and undercarriage members during loadout will undergo dry decontamination procedures. Dry decontamination consists of the use of brooms and other hand tools to remove accumulated soil, from vehicles prior to leaving the work area. Once loadout of the soil has been completed, the roadways shall be cleaned where visible soil has been deposited during transportation.

2.3.3.3 Manifesting

The appropriate documentation, (i.e., manifests) will accompany each load of soil/material to the intended disposal or recycling facility. The manifest will provide space for identifying the nature of the waste being transported, the date and time that the waste leaves the Site, the truck identification number, and the estimated weight/volume transported will be provided with each truck. The manifest form will be signed by a Bridge representative before the material leaves the Site; by the truck driver before the truck leaves the Site; and by a representative of the facility when the load is received at the disposal facility. Upon receipt of the material, the disposal facility will be required to send one copy of the manifest, completed with all appropriate signatures and final weight information, to Bridge and Engineer.

Waste removed from the Site shall only be transported to facilities which have been approved by Engineer and Bridge. Waste removed from the Site shall only be transported by transportation trucking companies which have received prior approval to the designated disposal/recycling facility.

In the event of an off-site spill during transportation, the transportation subcontractor will immediately take all necessary action to prevent, abate, or minimize the additional release or threat of release of any soil. Off-site spills of soil shall be collected, stored and disposed of with similar Site materials. Any “clean” materials potentially contaminated by an off-site spill shall be excavated and disposed of with the soils that caused the contamination, or shall be cleaned and restored to previous existing conditions, to the satisfaction of local authorities having jurisdiction, Bridge and Engineer.

2.3.3.4 Traffic Management Plan

Prior to the off-site disposal of any material, a Construction Traffic Management Plan (CTMP) will be prepared and will include the following:

- Detail of traffic routes used by construction vehicles on the Site;
- Detail of traffic routes used by construction vehicles from the Site to the disposal facility;
- The number and type of vehicles to be used during the project;
- Speed limits to be observed along routes to and from the Site; and
- Behavioral safety requirements for vehicle drivers to/from the Site and within the Site.

3. Soil Erosion and Sediment Control Measures

Due to the nature and extent of the development work, an ESC plan has been prepared in accordance with state, county and local soil conservation laws and regulations. The ESC plan should, at a minimum, include:

- Narrative description of the project, temporary and permanent ESC procedures, pre- and post-construction stormwater runoff patterns, and Site restoration;
- Calculations, as needed, for stormwater runoff and stability analyses;
- Various Site maps (quadrangle, soils, wetlands (if needed), etc.); and
- Design drawings, including pre- and post-construction elevations, cap locations, ESC controls, limits of disturbance, staging areas, details and required notes.

It is anticipated that stormwater encountered during redevelopment activities will be managed via on-Site ESCs and stored in temporary detention basins and sampled prior to determining where the water will be discharged. Bridge is evaluating the potential for discharge to the Philadelphia Water Department via a groundwater discharge permit. If required, an addendum to the SMP will be completed that details the means and mechanisms on managing stormwater.

Installed ESC measures will be inspected, maintained and replaced (as needed) throughout the duration of the development work. Vegetation is to only be cleared on an as needed basis to ensure that ESC measures remain in place.

4. Fluids Management

With regard to the proposed redevelopment and the potential for adverse impacts to groundwater, the development activities do not call for encountering groundwater with the exception of the potential to do so in the very limited case where utilities are installed. In addition to the limited scenarios where groundwater may be encountered, there is the potential of generating stormwater during precipitation events.[4] If it is determined that a Temporary Groundwater Discharge Permit will be need, the permit will be obtained from the Philadelphia Water Department that will allow for the discharge of groundwater and/or stormwater through the City's sewer system. Prior to discharge, the water will be collected and containerized in frac tanks (or similar). The requirements of the permit will determine if treatment and/or sampling of the fluid is necessary prior to discharge. Otherwise, these liquids will be handled, transported and disposed/recycled in accordance with applicable local, State and Federal regulations.

With regard to impacts to surface water, Bridge will be implementing a series of ESCs that will mitigate any impacts to surface waters (i.e. Delaware River).

[4] Care will be taken to minimize the amount of water in the area of excavation by employing diversion berms or other approved applicable techniques. Proper controls will be employed to minimize erosion and sediment transport of which details will be provided within the ESC plan.

5. Quality Assurance/Quality Control

All construction activities associated with the redevelopment of the Site will be conducted in a safe and prudent manner so that unreasonable hazards to workers and the public are minimized. Prior to initiating work activities, workers shall be trained to ensure a proper understanding of all aspects of their job including:

- Understanding their role and location at the Site;
- Traffic patterns and heavy equipment operations;
- Recognizing, and eliminating or avoiding hazards;
- Understanding flagger signals and safety colors;
- Knowing communication methods and alarms;
- Knowing how to work next to traffic and heavy equipment in a way that prevents accidents;
- Being as visible as possible; and
- Knowing how to operate equipment and vehicles, and specifically prevent rollovers.

This training will be conducted before an individual is allowed to work in the activity area and whenever operations change in the activity area. Additionally, tailgate safety meetings will be conducted on a weekly basis to specifically discuss the work planned for each day and the means by which to prevent incidents.

6. Health and Safety Requirements

A Site-specific Health and Safety Plan (HASP) will be prepared, which will be consistent with the requirements of Occupational Safety and Health Administration OSHA) (29 CFR 1910 and 1926) and all other federal, state and local authorities. In addition, the Site will be secured during all re-development activities in a manner to limit potential human and ecological exposure to contaminated media.

Dust shall be minimized to the greatest extent possible by implementing best management dust suppression practices by utilizing water trucks, street sweepers, misters, etc. Dust monitoring may be conducted by Engineer to evaluate the potential concern of affecting air quality. Proper measures will be taken to meet regulatory requirements to minimize and control dust during construction activities. Dust control during the excavation process is the main engineering control used to minimize potentially contaminated material from becoming airborne and affecting either the worker or environment.

7. Documentation of Soil Reuse, Staging and Placement

All Restricted Use Soils excavated at the Site will be subject to the below described documentation practices. An ongoing log will be maintained to track the soil origin and end use location. At a minimum the soil tracking log will include the following:

- Unique pile identifier code;
- Date and location of original excavation;
- Estimated volume;
- Placement depth, thickness, and aerial extent;
- Date of placement; and
- Lab data summarizing sol characterization activities for soil and material warranting offsite disposal (if warranted).

At the completion of the project, a comprehensive report will be prepared that will summarize the soil management activities as well as detail the new enhanced engineering controls.

8. Conclusions

This SMP has been developed to assist in the redevelopment of the Site and to ensure the requirements detailed within Arcadis' July 2021, *Remedial Investigation Report and Cleanup Plan* (provided as **Attachment A**) are adhered to. In addition, and as will be detailed within daily inspection logs, all soils and surface cover material that are disturbed and located within the Restricted Use Areas will remain within the Restricted Use Areas and will be repaired at a minimum to the pre-construction elevation (or greater) with material similar (or equally protective) composition.

DESCRIPTION OF NEED FOR GENERAL PERMITS

GP-3 STREAM BANK STABILIZATION: 2' OF CLEAN FILL IS REQUIRED PER THE ACT 2 PROGRAM. THE STREAM BANK AT THE DELAWARE RIVER WILL NEED TO BE STABILIZED TO PREVENT EROSION ALONG THE SHORE LINE.

GP-4 OUTFALL STRUCTURE: THE SITE IS MANAGED BY ABOVEGROUND BASINS, UNDERGROUND BASINS, AND A RAIN GARDEN. A SMALL PORTION OF THE SITE DRAINS TO RICHMOND STREET, WHILE THE MAJORITY OF THE SITE DRAINS TO THE DELAWARE RIVER. THE PROPOSED OUTFALL DISCHARGES TO THE DELAWARE RIVER IN THE SAME LOCATION AS AN EXISTING SITE DISCHARGE THAT IS IN POOR CONDITION.

PROPOSED WETLAND MITIGATION: THREE POCKETS OF ISOLATED WETLANDS THAT ARE CENTRALLY LOCATED ON-SITE ARE TO BE DISTURBED BY THE PROPOSED ACT 2 REMEDIATION AND DEVELOPMENT. WETLAND MITIGATION WILL OCCUR ON-SITE AT AN APPROXIMATE 2:1 RATIO.

DELAWARE RIVER & CHAPTER 93 DESIGNATION

THE SUBJECT SITE DISCHARGES TO THE DELAWARE RIVER WATERSHED. THE DELAWARE RIVER HAS A WWF (WARM WATER FISHES) & MF (MIGRATORY FISHES) CHAPTER 93 CLASSIFICATION.

DENOTES PERMANENT DISTURBANCE AREA

50 25 12.5 0 50

1"= 50'

GP-3 GENERAL NOTES

1. CONSTRUCTION OF THE BANK REHABILITATION, BANK PROTECTION PROJECT OR REMOVAL OF A GRAVEL BAR SHOULD NOT CONSTRICT OR INCREASE THE NORMAL CHANNEL WIDTH. THE CONFIGURATION OF THE SHORELINE SHALL REMAIN SUBSTANTIALLY THE SAME AND THE WORK SHALL ALIGN SMOOTHLY WITH, AND NOT PROJECT FURTHER INTO THE CHANNEL THAN ADJACENT UPSTREAM AND DOWNSTREAM BANKS. THE UPSTREAM AND DOWNSTREAM ENDS OF A BANK REHABILITATION OR BANK PROTECTION PROJECT SHALL BE KEYED INTO THE STREAM BANK TO ENSURE STABILITY.
2. CONSTRUCTION AND OTHER ACTIVITIES AUTHORIZED BY THIS GENERAL PERMIT SHALL BE PERFORMED IN A MANNER THAT MINIMIZES USE OF EQUIPMENT WITHIN THE STREAM CHANNEL OR BODY OF WATER.
3. BANK REHABILITATION, BANK PROTECTION AND GRAVEL BAR REMOVAL SHALL TAKE PLACE DURING PERIODS WHEN THE STREAM IS AT LOW FLOW.
4. TO THE GREATEST EXTENT POSSIBLE, THE PROJECT SHALL BE DESIGNED AND CONSTRUCTED IN A MANNER WHICH WILL (A) PREVENT PERMANENT OR LONG-TERM ADVERSE CHANGES IN WATER QUALITY, (B) MINIMIZE ALTERATIONS IN NATURAL AQUATIC HABITAT AND (C) MAINTAIN NATURAL STREAMFLOW VELOCITIES AND MIXING PATTERNS.
5. THE PLACEMENT OF FILL HIGHER THAN THE ELEVATION OF THE EXISTING STREAM BANKS, THE CONSTRUCTION OF LEVEES, THE REALIGNMENT OR RELOCATION OF THE CHANNEL, DREDGING ACTIVITIES IN WATER AND EXCAVATION BELOW EXISTING WATER LEVEL ARE NOT AUTHORIZED BY THIS GENERAL PERMIT.
6. BANK REHABILITATION, BANK PROTECTION AND GRAVEL BAR REMOVAL PROJECTS SHALL NOT EXTEND ACROSS ADJACENT PROPERTY LINES WITHOUT THE WRITTEN PERMISSION OF ALL AFFECTED PROPERTY OWNERS.
7. DURING CONSTRUCTION ACTIVITIES, ALL PUBLIC AND PRIVATE PROPERTY INCLUDING EXISTING VEGETATION, LANDSCAPE FEATURES AND MONUMENTS WITHIN, ALONG AND ADJACENT TO THE WORK AREA, SHALL BE PROTECTED AND PRESERVED TO THE MAXIMUM DEGREE POSSIBLE. THIS SHALL INCLUDE, BUT NOT BE LIMITED TO, PRECAUTIONS TAKEN TO MINIMIZE DAMAGE, EROSION, INJURY OR DESTRUCTION; PREVENT POLLUTION; PROVIDE PROTECTION OF ALL TREES AND OTHER WOODY PLANTS; SPECIAL CARE BEING TAKEN TO PROTECT THE NATURAL VEGETATION AND SURROUNDINGS TO INCLUDE ALL NATURAL DRAINAGEWAYS, PONDS, LAKES, WETLANDS, WOODS AND FIELDS; AND STORAGE OF MATERIALS IN SUCH MANNER TO PREVENT LEACHING WHICH WOULD BE INJURIOUS TO SOILS AND TO PLANTS. PRECAUTIONS SHOULD BE TAKEN TO PREVENT DAMAGE TO PIPES, CONDUITS AND OTHER UNDERGROUND STRUCTURES.
8. ONLY CLEAN, NONPOLLUTING MATERIALS SHALL BE USED FOR BANK REHABILITATION AND PROTECTION PROJECTS IN ORDER TO MINIMIZE EXCESSIVE TURBIDITY BY LEACHING OF FINES AS WELL AS TO PRECLUDE ENTRANCE OF UNDESIRABLE CHEMICAL CONSTITUENTS TO THE WATERCOURSE BY NATURAL RUNOFF OR LEACHING.

GP-4 GENERAL NOTES

1. EACH INTAKE AND OUTFALL STRUCTURE SHALL BE CONSTRUCTED IN SUCH MANNER SO THAT THERE IS NO INTERFERENCE WITH ANY NAVIGATION ON THE STREAM, MIGRATION OF FISH OR THE PASSAGE OF FLOOD FLOWS.
2. INTAKE AND OUTFALL STRUCTURES AUTHORIZED UNDER THIS GENERAL PERMIT SHALL NOT INTERFERE WITH STREAM USES AS DESIGNATED IN CHAPTER 93 OF THE DEPARTMENT'S RULES AND REGULATIONS.
3. INTAKE AND OUTFALL STRUCTURES HEREIN AUTHORIZED SHALL BE PROPERLY MAINTAINED WHICH INCLUDES THE REMOVAL OF ANY ACCUMULATION OF DEBRIS.
4. THIS GENERAL PERMIT IS NOT TO BE CONSTRUED AS APPROVAL OF DISCHARGES INTO THE RECEIVING STREAM OR BODY OF WATER WHICH MAY REQUIRE CERTIFICATION UNDER 401(A) OF THE FEDERAL WATER POLLUTION CONTROL ACT (33 USCA §1341(A)) OR OTHER RELEVANT STATE STATUTES.
5. THIS GENERAL PERMIT AUTHORIZES THE CONSTRUCTION ONLY OF THOSE OUTFALL STRUCTURES HAVING A PIPE OUTFALL 36 INCHES IN DIAMETER OR LESS.

PLEASE REFER TO CONSTRUCTED WETLAND NOTES ON SHEET C-705 FOR SEQUENCE OF CONSTRUCTION.

CONSTRUCTED WETLAND NOTES

SEQUENCE OF CONSTRUCTION

1. ONCE THE STORMWATER WETLAND HAS BEEN EXCAVATED, THE WETLAND SHOULD BE GRADED TO CREATE THE MAJOR INTERNAL FEATURES (POOL, AQUATIC BENCH, DEEP-WATER CHANNELS, ETC).

2. TOP SOIL AND/OR WETLAND MULCH IS ADDED TO THE STORMWATER WETLAND EXCAVATION. SINCE DEEP SUBSOILS OFTEN LACK THE NUTRIENTS AND ORGANIC MATTER TO SUPPORT VIGOROUS PLANT GROWTH, THE ADDITION OF MULCH OR TOPSOIL IS IMPORTANT. IF IT IS AVAILABLE, WETLAND MULCH IS PREFERABLE TO TOPSOIL. AFTER THE MULCH OR TOPSOIL HAS BEEN ADDED, THE STORMWATER WETLAND NEEDS TO BE GRADED TO ITS FINAL ELEVATIONS. ALL WETLAND FEATURES ABOVE THE NORMAL POOL SHOULD BE STABILIZED TEMPORARILY. SEE SOIL EROSION AND SEDIMENT CONTROL PLAN FOR SEED SPECIFICATION.

3. AFTER GRADING TO FINAL ELEVATIONS, THE POND DRAIN SHOULD BE CLOSED AND THE POOL ALLOWED TO FILL. USUALLY NOTHING SHOULD BE DONE TO THE STORMWATER WETLAND FOR SIX TO NINE MONTHS OR UNTIL THE NEXT PLANTING SEASON. A GOOD DESIGN RECOMMENDATION IS TO EVALUATE THE WETLAND ELEVATION DURING A STANDING PERIOD OF APPROXIMATELY SIX MONTHS. DURING THIS TIME THE STORMWATER WETLAND CAN EXPERIENCE STORM FLOWS AND INUNDATION, SO THAT IT CAN BE DETERMINED WHERE THE PONDSCAPING ZONES ARE LOCATED AND WHETHER OR NOT THE FINAL GRADE AND MICROTOPOGRAPHY WILL PERSIST OVERTIME.

4. BEFORE PLANTING, THE STORMWATER WETLAND DEPTHS SHOULD BE MEASURED TO THE NEAREST INCH TO CONFIRM PLANTING DEPTH. THE PONDSCAPE PLAN MAY BE MODIFIED AT THIS TIME TO REFLECT ALTERED DEPTHS OR AVAILABILITY OF PLANT STOCK.

5. EROSION CONTROLS SHOULD BE STRICTLY APPLIED DURING THE STANDING AND PLANTING PERIODS. ALL AREAS ABOVE THE NORMAL POOL ELEVATION SHOULD BE VEGETATIVELY STABILIZED DURING THE STANDING PERIOD.

6. THE STORMWATER WETLAND SHOULD BE DE-WATERED AT LEAST THREE DAYS BEFORE PLANTING FOR EASE OF PLANTING.

7. DURING THE INITIAL PLANTING PRECAUTIONS SHOULD BE UNDERTAKEN TO PREVENT AND PROHIBIT ANIMALS FROM GRAZING UNTIL PLANT COMMUNITIES ARE WELL ESTABLISHED. SUCH PRECAUTIONS COULD BE DEER FENCING, MUSKRAT TRAPPING, PLANTING AFTER SEASONAL BIRD MIGRATIONS OR ATTRACTING BIRDS OF PREY AND BATS TO CONTROL NUTRIA POPULATIONS.

OPERATIONS AND MAINTENANCE NOTES:

1. CONSTRUCTED STORMWATER WETLANDS REQUIRE CONSIDERABLE ROUTINE MAINTENANCE, BUT DO NOT REQUIRE LARGE, INFREQUENT SEDIMENT REMOVAL UNLIKE CONVENTIONAL POND SYSTEMS THAT REQUIRES RELATIVELY MINOR ROUTINE MAINTENANCE AND EXPENSIVE SEDIMENT REMOVAL AT INFREQUENT INTERVALS.

2. CAREFUL OBSERVATION OF THE SYSTEM OVER TIME IS REQUIRED IN THE FIRST THREE YEARS AFTER CONSTRUCTION. WITHIN THE FIRST GROWING SEASON OR UNTIL IT IS DETERMINED THAT THE SYSTEM IS ESTABLISHED, FREQUENT INSPECTIONS WILL BE REQUIRED, POSSIBLY BIWEEKLY OR MONTHLY BASIS. FOLLOWING THIS, TWICE A YEAR INSPECTIONS ARE NEEDED DURING BOTH THE GROWING AND NON-GROWING SEASON. DATA GATHERED DURING THESE INSPECTIONS SHOULD BE RECORDED , MAPPED AND ASSESSED. THE FOLLOWING OBSERVATIONS SHOULD BE MADE DURING THE INSPECTIONS:
   a. TYPES AND DISTRIBUTION OF DOMINANT WETLAND PLANTS IN THE MARSH;
   b. THE PRESENCE AND DISTRIBUTION OF PLANTED WETLAND SPECIES; THE PRESENCE AND DISTRIBUTION OF VOLUNTEER WETLAND SPECIES; SIGNS THAT VOLUNTEER SPECIES ARE REPLACING THE PLANTED WETLAND SPECIES;
   c. PERCENTAGE OF UNVEGETATED STANDING WATER (EXCLUDING THE DEEP WATER CELLS WHICH ARE NOT SUITABLE FOR EMERGENT PLANT GROWTH);
   d. THE MAXIMUM ELEVATION AND THE VEGETATIVE CONDITION IN THIS ZONE, IF THE DESIGN ELEVATION OF THE NORMAL POOL IS BEING MAINTAINED FOR WETLANDS WITH EXTENDED ZONES;
   e. STABILITY OF THE ORIGINAL DEPTH ZONES AND THE MICROTOPOGRAPHIC FEATURES;
   f. ACCUMULATION OF SEDIMENT IN THE FOREBAY AND MICROPOOL;
   g. SURVIVAL RATE OF PLANTS IN THE WETLAND BUFFER;
   h. REGULATION THE SEDIMENT INPUT TO THE WETLAND IS THE PRIORITY MAINTENANCE ACTIVITY. THE MAJORITY OF SEDIMENTS SHOULD BE TRAPPED AND REMOVED BEFORE THEY REACH THE WETLANDS EITHER IN THE FOREBAY OR IN A POND COMPONENT. GRADUAL SEDIMENT ACCUMULATION IN THE WETLAND RESULT IN REDUCED WATER DEPTHS AND CHANGES IN THE GROWING CONDITIONS FOR THE EMERGENT PLANTS. FURTHERMORE, SEDIMENT REMOVAL WITHIN THE WETLAND CAN DESTROY THE WETLAND PLANT COMMUNITY;
   i. SHALLOW MARSH AND EXTENDED DETENTION WETLAND DESIGNS INCLUDE FOREBAYS TO TRAP SEDIMENT BEFORE REACHING THE WETLAND. THEREFORE BAYS SHOULD BE CLEANED OUT EVERY YEAR;
   j. CLEAN OUTS AND DISCHARGE LOCATIONS SHOULD BE INSPECTED MORE FREQUENTLY. INSPECTIONS FOR THEM COULD COINCIDE WITH ABOVE NORMAL OR EXTENDED PERIOD RAINFALL, RATHER THAN JUST INCREASING THE INSPECTION INTERVALS. THUS, IF THERE ARE PERIODS OF DROUGHT OR SMALL INFREQUENT EVENTS IT WOULD NOT BE NECESSARY FOR AN INSPECTION.

LOCATION OF ALL SURFACE WATERS AND THEIR CLASSIFICATION UNDER CHAPTER 93

§102.4(b)(5)(v)

THE SUBJECT SITE IS LOCATED WITHIN THE DELAWARE DIRECT WATERSHED, WHICH HAS A WWF (WARM WATER FISHES) & MF (MIGRATING FISH) CHAPTER 93 CLASSIFICATION.

RECYCLING OR DISPOSAL OF MATERIALS

§102.4(b)(5)(xi)

THE FOLLOWING IS A LIST THAT INCLUDES, BUT THAT IS NOT LIMITED TO, THE POTENTIAL CONSTRUCTION WASTES THAT MAY EXIST ON-SITE:
- CONCRETE CURB AND SIDEWALK
- ASPHALT
- E&S BMP - COMPOST FILTER SOCKS
- E&S BMP - TEMPORARY RISER
- E&S BMP - EROSION CONTROL MATTING
- E&S BMP - STONE INLET PROTECTION
- E&S BMP - STONE & CONCRETE BLOCK INLET PROTECTION
- E&S BMP - REGULATED FILL MATERIALS

ALL BUILDING MATERIALS AND WASTES SHALL BE REMOVED FROM THE SITE AND RECYCLED OR DISPOSED OF IN ACCORDANCE WITH THE DEPARTMENT'S SOLID WASTE MANAGEMENT REGULATIONS AT 25 Pa. CODE 260.1 ET SEQ., 271.1, AND 287.1 ET SEQ. NO BUILDING MATERIALS OR WASTES OR UNUSED BUILDING MATERIALS SHALL BE BURNED, BURIED, DUMPED, OR DISCHARGED AT THE SITE. BELOW IS A LIST OF METHODS FOR THE PROPER RECYCLING/DISPOSAL OF VARIOUS MATERIALS:

1.) DUST CONTROL - CONSTRUCTION TRAFFIC MUST ENTER AND EXIT THE SITE AT THE STABILIZED CONSTRUCTION ENTRANCE. THE PURPOSE IS TO TRAP DUST AND MUD THAT WOULD OTHERWISE BE CARRIED OFF-SITE BY CONSTRUCTION TRAFFIC. WATER TRUCKS WILL BE USED AS NEEDED DURING CONSTRUCTION TO REDUCE DUST GENERATED ON THE SITE. DUST CONTROL MUST BE PROVIDED BY THE CONTRACTOR TO A DEGREE THAT IS ACCEPTABLE TO THE LOCAL CONSERVATION DISTRICT. AFTER CONSTRUCTION, THE SITE WILL BE STABILIZED, WHICH WILL REDUCE THE POTENTIAL FOR DUST GENERATION.

2.) SOLID WASTE DISPOSAL - NO SOLID MATERIALS, INCLUDING BUILDING MATERIALS, ARE ALLOWED TO BE DISCHARGED FROM THE SITE WITH STORMWATER. ALL SOLID WASTE, INCLUDING DISPOSABLE MATERIALS INCIDENTAL TO THE MAJOR CONSTRUCTION ACTIVITIES, MUST BE COLLECTED AND PLACED IN CONTAINERS. THE CONTAINERS WILL BE EMPTIED AS NECESSARY BY A CONTRACT TRASH DISPOSAL SERVICE AND HAULED AWAY FROM THE SITE.

3.) SANITARY FACILITIES - ALL PERSONNEL INVOLVED WITH CONSTRUCTION ACTIVITIES MUST COMPLY WITH STATE AND LOCAL SANITARY OR SEPTIC SYSTEM REGULATIONS. TEMPORARY SANITARY FACILITIES WILL BE PROVIDED AT THE SITE THROUGHOUT THE CONSTRUCTION PHASE. THEY MUST BE UTILIZED BY ALL CONSTRUCTION PERSONNEL AND WILL BE SERVICED BY A LICENSED COMMERCIAL OPERATOR.

4.) WATER SOURCE - NON-STORMWATER COMPONENTS OF SITE DISCHARGE MUST BE CLEAN WATER. WATER USED FOR CONSTRUCTION WHICH DISCHARGES FROM THE SITE MUST ORIGINATE FROM A PUBLIC WATER SUPPLY OR PRIVATE WELL APPROVED BY THE STATE HEALTH DEPARTMENT. WATER USED FOR CONSTRUCTION THAT DOES NOT ORIGINATE FROM AN APPROVED PUBLIC SUPPLY MUST NOT DISCHARGE FROM THE SITE.

5.) CONCRETE WASTE FROM CONCRETE READY-MIX TRUCKS - DISCHARGE OF EXCESS OR WASTE CONCRETE AND/OR WASH WATER FROM CONCRETE TRUCKS WILL BE ALLOWED ON THE CONSTRUCTION SITE, BUT ONLY IN SPECIFICALLY DESIGNATED DIKED AREAS PREPARED TO PREVENT CONTACT BETWEEN THE CONCRETE AND/OR WASH WATER AND STORMWATER THAT WILL BE DISCHARGED FROM THE SITE.

GEOLOGIC FORMATIONS/SOIL CONDITIONS THAT MAY HAVE THE POTENTIAL TO CAUSE POLLUTION

CHANNEL

THERE ARE NO GEOLOGIC FORMATIONS OR SOIL CONDITIONS THAT COULD CAUSE CONTAMINANT POLLUTION DURING EARTH DISTURBANCE ACTIVITIES.

POTENTIAL THERMAL IMPACTS TO SURFACE WATERS

A POTENTIAL FOR THERMAL IMPACTS EXISTS IN INSTANCES WHERE SURFACE RUNOFF IS DIRECTLY CONVEYED TO A RECEIVING STREAM WITHOUT ADEQUATE ATTENUATION OR COOLING. TO AVOID THERMAL IMPACTS, THE FOLLOWING ARE PROPOSED: UNDERGROUND INFILTRATION BASIN, RETENTION/INFILTRATION EXISTING SWALES, EXISTING DEPRESSIONS, AND SUBSTANTIAL AMOUNTS OF VEGETATION AROUND EACH OF THESE BMP'S. ALL OF THESE MEASURES WILL HELP TO CONTROL RUNOFF VOLUME AND RATE AND THEREBY PROVIDE ADDITIONAL COOLING TIME, THEREBY MINIMIZING THERMAL IMPACTS TO THE RECEIVING STREAM.

TYPES, DEPTH, SLOPE, LOCATIONS, AND LIMITATIONS OF THE SOILS

§102.4(b)(5)(ii)

SOIL DESCRIPTIONS

SOIL	DESCRIPTION	SOIL GROUP
Ub	- URBAN LAND, 0 TO 8 PERCENT SLOPES	C

SOIL USE LIMITATIONS AND THEIR RESOLUTIONS PROVIDED

CONTRACTOR SHALL CONSULT WITH GEOTECHNICAL ENGINEER TO DETERMINE SOIL LIMITATIONS AND RESOLUTIONS SPECIFIC TO THIS PROJECT.

1. SOIL TYPES POORLY SUITED AS SOURCES OF TOPSOIL RESTRICT OR PLACE CONDITIONS ON PLANNING VEGETATIVE STABILIZATION. ACIDIC, LOW FERTILITY, EXCESSIVE DRYNESS AND EXCESSIVE WETNESS LIMIT PLANT GROWTH.

RESOLUTIONS: IDENTIFYING AND RESOLVING CHARACTERISTICS, THAT RENDER THE SOIL TYPES POORLY, SUITED AS TOPSOIL.

2, ACIDIC SOIL TYPES EXHIBITING PH REACTION VALUES LOWER THAN ABOUT 5,5, LIMIT VEGETATIVE STABILIZATION, SOIL TESTS MIGHT BE NECESSARY TO DETERMINE SITE SPECIFIC PH REACTION.

RESOLUTIONS: APPLYING LIME CONSISTENT WITH RATES DETERMINED BY SOIL TESTING; SELECTING VEGETATIVE SPECIES TOLERANT TO ACIDIC SOIL CONDITIONS; AND IMPLEMENTING COMBINATIONS OF THESE AND/OR OTHER METHODS, SPECIFIC TOLERANCE INFORMATION IS PROVIDED IN TABLE 1 OF THE EROSION CONTROL & CONSERVATION PLANTINGS ON NONCROPLAND PUBLISHED BY PENN STATE.

3. LOW FERTILITY SOIL TYPES LACKING IN SUFFICIENT AMOUNTS OF ESSENTIAL PLANT NUTRIENTS SUCH AS: NITRPGEN, PHOSPHOROUS, POTASSIUM, SULFER, MAGNESIUM, CALCIUM, IRON, MANGANESE, BORON, CHLORINE, ZINC, COPPER AND MOLYBDENUM, LIMIT VEGETATION STABILIZATION. SOIL TESTS MIGHT BE NECESSARY TO DETERMINE SITE SPECIFIC SOIL FERTILITY.

RESOLUTIONS: INCORPORATING SOIL NUTRIENTS CONSISTENT WITH RATES DETERMINED BY SOIL TESTING; SELECTIVE VEGETATIVE SPECIES TOLERANT TO LOW FERTILITY SOIL CONDITIONS, AND IMPLEMENTING COMBINATIONS OF THESE AND/OR OTHER METHODS. SPECIFIC TOLERANCE INFORMATION IS PROVIDED IN TABLE 1 OF THE EROSION CONTROL & CONSERVATION PLANTINGS ON NONCROPLAND PUBLISHED BY PENN STATE.

4, ERODIBLE SOIL TYPES EXHIBITING K VALUES GREATER THAN 0,36 OR PLASTICITY INDEX VALUES LOWER THAN 10, LIMIT VEGETATIVE STABILIZATION OF CHANNELS.

RESOLUTIONS: TEMPORARY CHANNEL LINING, PROVIDING PERMANENT CHANNEL LINING, DECREASING CHANNEL GRADE, INCREASING CHANNEL WIDTH, SELECTING VEGETATIVE WITH GREATER RETARDANCE, SELECTING PERMANENT LININGS OTHER THAN GRASSES, AND IMPLEMENTING COMBINATION OF THESE AND/OR METHODS, VEGETATIVE RETARDANCE INFORMATION IS PROVIDED IN TABLES 6 AND 7 OF THE EROSION AND SEDIMENT POLLUTION CONTROL MANUAL PUBLISHED BY PADEP.

5. WET SOIL TYPES HAVE EXCESSIVE ROOT ZONE AND SOIL MOISTURES. SOME SOIL SURVEYS INDICATE WETNESS, HIGH WATER TABLE AND FLOODING. THIS INDICATOR IS AFFECTED BY SOIL DISTURBANCE.

RESOLUTIONS: SELECTING VEGETATIVE SPECIES TOLERANT TO WET CONDITIONS, TILING VEGETATIVE AREAS, AND IMPLEMENTING COMBINATIONS OF THESE AND/OR OTHER METHODS. SPECIFIC TOLERANCE INFORMATION IS PROVIDED IN TABLE 1 OF THE EROSION CONTROL & CONSERVATION PLANTINGS ON NONCROPLAND PUBLISHED BY THE PENN STATE.

6. DRY SOIL TYPES LACK SUFFICIENT ROOT ZONE SOIL MOISTURES. THIS INDICATOR IS AFFECTED BY SOIL DISTURBANCE.

RESOLUTIONS: SELECTING VEGETATIVE SPECIES TOLERANT TO DRY CONDITIONS, IRRIGATING VEGETATED AREAS AND IMPLEMENTING COMBINATION OF THESE AND/OR OTHER METHODS. SPECIFIC TOLERANCE INFORMATION IS PROVIDED IN TABLE 1 OF THE EROSION CONTROL & CONSERVATION PLANTINGS ON NONCROPLAND PUBLISHED BY PENN STATE.

7. SOIL TYPES SUSCEPTIBLE TO SINKHOLE AND SOLUTION CHANNEL/CHAMBER FORMATION POSE LIMITATIONS ON LOCATING RESERVOIR AREAS OF SEDIMENT BASINS, SEDIMENT TRAPS, STORMWATER RETENTION BASINS, AND STORMWATER DETENTION BASINS.

RESOLUTIONS: LOCATING THOSE FACILITIES ON OTHER SOIL TYPES, LINING RESERVOIR AREAS WITH IMPERMEABLE LINNINGS, LIMITING STANDING WATER DEPTHS, LIMITING RETENTION TIMES AND IMPLEMENTING COMBINATIONS OF THESE AND/OR OTHER METHODS.

8. SOIL TYPES THAT EXHIBIT INSTABILITY IN POND EMBANKMENTS OR SUSCEPTIBILITY TO PIPING AND SEEPING POSE LIMITATIONS ON PLANNING EMBANKMENTS OF SEDIMENT BASINS, SEDIMENT TRAPS, STORMWATER RETENTION BASINS AND STORMWATER DETENTION BASINS.

RESOLUTIONS: IMPORTING OTHER SOIL FOR EMBANKMENT OF THOSE FACILITIES, LOCATING THOSE FACILITIES ON OTHER SOIL TYPES, LIMITING EMBANKMENT SLOPE STEEPNESS AND IMPLEMENTING COMBINATIONS OF THESE AND/OR OTHER METHODS.

9. SOIL THAT ARE DIFFICULT TO COMPACT, UNSUITABLE FOR WINTER GRADING, OR SUSCEPTIBLE TO FROST ACTION POSE LIMITATIONS ON PLANNING EMBANKMENTS OF SEDIMENT BASINS, SEDIMENT TRAPS, STORMWATER RETENTION BASINS AND STORMWATER DETENTION BASINS.

RESOLUTIONS: IMPORTING OTHER SOIL FOR EMBANKMENT OF THOSE FACILITIES, LOCATING THOSE FACILITIES ON OTHER SOIL TYPES, NOT CONSTRUCTING EMBANKMENTS DURING PERIODS PRONE TO FROST AND IMPLEMENTING COMBINATIONS OF THESE AND/OR OTHER METHODS

10. SUCCEPTIBILITY FOR THE DEVELOPMENT OF SINKHOLE WITHIN IDENTIFIED SOILS.

RESOLUTIONS: IN THE EVENT THAT PRESENCE OF A SINKHOLE IS DETECTED DURING THE COURSE OF WORK, CORRECTIVE MEASURES SHALL BE PERFORMED UNDER THE OBSERVATION AND GUIDANCE OF THE OWNER'S GEOTECHNICAL CONSULTANT.
EXCAVATE THE LOOSE, WET SOILS SURROUNDING THE SINKHOLE TO EXPOSE THE SINKHOLE "THROAT" (THE OPENING IN THE ROCK) AND THE ADJACENT STABLE SOILS/ROCK WHERE POSSIBLE. THE EXCAVATION SHALL EXTEND A MINIMUM OF TWO FEET (2') BEYOND THE STABLE SOILS OR TO THE ROCK SURFACE, WHICHEVER IS ENCOUNTERED FIRST.
FILL THE EXPOSED SINKHOLE "THROAT" WITH LEAN CONCRETE TO BLOCK THE MIGRATION OF THE UPPER LAYERS OF SOIL THROUGH THE ROCK OPENING. AFTER CONCRETE HAS CURED OVERNIGHT BACKFILL THE REMAINDER OF THE EXCAVATION WITH CLAYEY SOILS TO PROVIDE A LOW PERMEABILITY BARRIER. THE CLAYEY SOILS SHALL BE PLACED IN 8" LIFTS AND EACH LIFT COMPACTED BY REPEATED PASSES OF THE COMPACTION EQUIPMENT UNTIL STABLE. CARE SHALL BE TAKEN TO ASSURE THAT THE SOIL AT THE EDGES OF THE EXCAVATION ARE WELL COMPACTED.

E&S PLAN DESIGNED AND IMPLEMENTED TO BE CONSISTENT WITH PCSM PLAN

§102.4(b)(5)(xiv)

REGARDING THE LOCATIONS OF EXISTING RIPARIAN BUFFERS RELATIVE TO THE LIMIT OF DISTURBANCE AND WHETHER PROPOSED INFILTRATION FACILITIES ARE OUTSIDE OF PROPOSED GRADING AREAS, NOTE THE FOLLOWING:
- THERE ARE NO EXISTING OR PROPOSED RIPARIAN BUFFERS.
- THERE ARE NO PROPOSED INFILTRATION BMPs OUTSIDE OF PROPOSED GRADING AREAS.

EXISTING/PROPOSED RIPARIAN FOREST BUFFERS

§102.4(b)(5)(xv)

REGARDING EXISTING OR PROPOSED RIPARIAN FOREST BUFFERS, NOTE THE FOLLOWING:
- THERE ARE NO EXISTING/PROPOSED RIPARIAN FOREST BUFFERS LOCATED WITHIN OR OUTSIDE THE LIMITS OF DISTURBANCE FOR THIS PROJECT.

SEQUENCE OF CONSTRUCTION

SEQUENCE OF CONSTRUCTION

A. ALL EARTH DISTURBANCE ACTIVITIES SHALL PROCEED IN ACCORDANCE WITH THE FOLLOWING SEQUENCE. EACH STAGE SHALL BE COMPLETED IN COMPLIANCE WITH CHAPTER 102 REGULATIONS BEFORE ANY FOLLOWING STAGE IS INITIATED. CLEARING AND GRUBBING SHALL BE LIMITED ONLY TO THOSE AREAS DESCRIBED IN EACH STAGE. UPON COMPLETION OR TEMPORARY CESSATION OF THE EARTH DISTURBANCE ACTIVITY THAT WILL EXCEED FOUR (4) DAYS, OR ANY STAGE THEREOF, THE PROJECT SITE SHALL BE IMMEDIATELY STABILIZED WITH THE APPROPRIATE TEMPORARY OR PERMANENT STABILIZATION.
B. NO WORK CAN BEGIN WITHIN THE FLOODWAY/ WETLANDS AREA UNTIL CHAPTER 105 AND USACE AUTHORIZATIONS ARE OBTAINED
C. REFERENCES TO 'PADEP' USED THROUGHOUT THIS SEQUENCE ARE MEANT TO REFER TO THE PENNSYLVANIA DEPARTMENT OF ENVIRONMENTAL PROTECTION.
D. AT LEAST SEVEN (7) DAYS BEFORE STARTING ANY EARTH DISTURBANCE ACTIVITIES, THE OPERATOR SHALL INVITE ALL CONTRACTORS INVOLVED IN THOSE ACTIVITIES INCLUDING, BUT NOT LIMITED TO: THE LANDOWNER AND/OR THEIR REPRESENTATIVE, GENERAL CONTRACTOR, ALL APPROPRIATE MUNICIPAL OFFICIALS AND A REPRESENTATIVE OF THE PADEP FOR AN ON-SITE PRE-CONSTRUCTION MEETING. ALSO, AT LEAST THREE (3) DAYS BEFORE STARTING ANY EARTH DISTURBANCE ACTIVITIES, ALL CONTRACTORS INVOLVED IN THOSE ACTIVITIES SHALL NOTIFY THE PENNSYLVANIA ONE CALL SYSTEM INC. AT 1-800-242-1776 FOR BURIED UTILITIES LOCATION.
E. BEFORE INITIATING ANY REVISION TO THE APPROVED EROSION AND SEDIMENT CONTROL PLAN OR REVISIONS TO OTHER PLANS WHICH MAY AFFECT THE EFFECTIVENESS OF THE APPROVED E&S CONTROL PLAN, THE OPERATOR MUST RECEIVE APPROVAL OF THE REVISIONS FROM THE PADEP. THE OPERATOR SHALL ASSURE THAT THE APPROVED EROSION AND SEDIMENT CONTROL PLAN IS PROPERLY AND COMPLETELY IMPLEMENTED. IMMEDIATELY UPON DISCOVERING UNFORESEEN CIRCUMSTANCES POSING THE POTENTIAL FOR ACCELERATED EROSION AND/OR SEDIMENT POLLUTION, THE OPERATOR SHALL CONTACT THE PADEP AND IMPLEMENT APPROPRIATE BEST MANAGEMENT PRACTICES TO ELIMINATE POTENTIAL FOR ACCELERATED EROSION AND/OR SEDIMENT POLLUTION.
F. THE TERM 'PERMANENT STABILIZATION' USED THROUGHOUT THIS SEQUENCE IS MEANT TO DESCRIBE THE PROPER PLACING, GRADING, CONSTRUCTING, REINFORCING, LINING, AND COVERING OF SOIL, ROCK OR EARTH TO ENSURE THEIR PERMANENT RESISTANCE TO EROSION, SLIDING OR OTHER MOVEMENT. FOR AN EARTH DISTURBANCE TO BE PERMANENTLY STABILIZED, THE DISTURBED AREA SHALL BE COVERED WITH ONE OF THE FOLLOWING: A MINIMUM UNIFORM 70% PERENNIAL VEGETATIVE COVER, WITH A DENSITY CAPABLE OF RESISTING ACCELERATED EROSION AND SEDIMENTATION; OR AN ACCEPTABLE BMP THAT PERMANENTLY MINIMIZES ACCELERATED EROSION AND SEDIMENTATION.
G. FOR EACH OF THE 'CRITICAL STAGES' SPECIFIED BELOW, THE PERMITTEE SHALL PROVIDE ENGINEERING OVERSIGHT. A LICENSED PROFESSIONAL OR DESIGNEE KNOWLEDGEABLE IN THE DESIGN AND CONSTRUCTION OF SAID BMP, PREFERABLY THE DESIGN ENGINEER, SHALL CONDUCT THE OVERSIGHT.
H. SEDIMENT CONTROL FACILITIES MUST BE PROTECTED FROM UNAUTHORIZED ACTS OF THIRD PARTIES. REFER ALSO TO THE MONITORING, INSPECTION AND REPORTING REQUIREMENTS PROVIDED HEREIN FOR ADDITIONAL REQUIREMENTS DURING CONSTRUCTION.
I. AS SOON AS SLOPES, CHANNELS, DITCHES AND OTHER DISTURBED AREAS REACH FINAL GRADE, THEY MUST BE STABILIZED. WHEN FINAL GRADE IS ACHIEVED DURING NON-GERMINATING MONTHS, THE AREA SHOULD BE MULCHED UNTIL THE BEGINNING OF THE NEXT PLANTING SEASON. AS DISTURBED AREAS WITHIN A PROJECT APPROACH FINAL GRADE, PREPARATIONS SHOULD BE MADE FOR SEEDING AND MULCHING TO BEGIN (I.E. ANTICIPATE THE COMPLETION DATE AND SCHEDULE THE SEEDER). IN NO CASE SHOULD AN AREA EXCEEDING 15,000 SQUARE FEET, WHICH IS TO BE STABILIZED BY VEGETATION, REACH FINAL GRADE WITHOUT BEING SEEDED AND MULCHED. WAITING UNTIL EARTHMOVING IS COMPLETED BEFORE MAKING PREPARATIONS FOR SEEDING AND MULCHING IS NOT ACCEPTABLE. SEEDING AND MULCHING REQUIREMENTS ARE SPECIFIED IN THE GENERAL CONSERVATION NOTES AND SPECIFICATIONS.
J. PLEASE REFER TO THE ENVIRONMENTAL PLAN, SHEET 2, AND ASSOCIATED SOIL MANAGEMENT PLAN FOR PROCEDURES TO MANAGE CONTAMINATED OR POTENTIALLY CONTAMINATED MATERIALS DURING CONSTRUCTION.
K. CONTRACTOR MUST DETERMINE IF AN INDUSTRIAL GROUNDWATER DISCHARGE PERMIT FROM THE PHILADELPHIA WATER DEPARTMENT INDUSTRIAL WASTE UNIT IS REQUIRED PRIOR TO DISCHARGE OF GROUNDWATER OR STORMWATER INTO CITY-OWNED INFRASTRUCTURE. CONTACT PWD INDUSTRIAL WASTE UNIT AT 215-685-6085 FOR INFORMATION.
L. FOR CONTAMINATED SITES PROPOSING TO ATTAIN REMEDIATION STANDARD(S) OUTLINED IN THE LAND RECYCLING AND ENVIRONMENTAL REMEDIATION STANDARDS ACT (ACT 2) - THE PERMITTEE IS RESPONSIBLE FOR ASSURING THAT THE REMEDIATION FOLLOWS ALL REPORTS/PLANS/PROCEDURES APPROVED BY THE DEPARTMENTS ENVIRONMENTAL CLEANUP AND BROWNFIELDS (ECB) PROGRAM. GROUNDWATER EXPOSURE PATHWAYS MUST BE PROPERLY MANAGED TO PREVENT GROUNDWATER POLLUTION. THE REGIONAL ECB PROGRAM SHOULD BE CONTACTED AT 484.250.5960 FOR ANY REMEDIATION QUESTIONS."
M. IF ANY OF THE REQUIREMENTS OR APPROVALS UNDER THE ENVIRONMENTAL CLEANUP AND BROWNFIELDS PROGRAM; SOLID WASTE MANAGEMENT PROGRAM; OR AIR QUALITY PROGRAM REQUIRE MODIFICATIONS, PLEASE CONTACT THOSE PROGRAMS DIRECTLY."
N. CONTAMINATED AREAS SHALL BE AVOIDED TO THE EXTENT THEY ARE NOT WITHIN THE AREA OF CONSTRUCTION. SOIL EROSION AND SEDIMENT POLLUTION CONTROL MEASURES WILL BE INSTALLED, INSPECTED, MAINTAINED AND REPLACED (AS NEEDED) THROUGHOUT THE DURATION OF THE DEVELOPMENT WORK.

STAGE I:

1.INSTALL CONSTRUCTION ENTRANCE ALONG ORTHODOX STREET AS DESIGNATED ON THE PLANS. ENTRANCE SHOULD BE INSPECTED PRIOR TO CONSTRUCTION AND SHOULD BE REFRESHED AS NEEDED.

2.INSTALL ALL PERIMETER COMPOST FILTER SOCKS, CONSTRUCTION FENCING & INLET PROTECTION WITHIN THE DESIGNATED LIMIT OF DISTURBANCE AS INDICATED ON THE PLANS. ONLY LIMITED CLEARING AND GRUBBING NECESSARY TO INSTALL THE PERIMETER EROSION AND SEDIMENT POLLUTION CONTROLS IS PERMITTED.

3.CRITICAL STAGE #1 INSTALL SEDIMENT BASINS - BEGIN NECESSARY EARTHWORK REQUIRED TO CONSTRUCT SEDIMENT BASIN A & B. INSTALL THE PERMANENT STORM CONVEYANCE SYSTEM FROM EW-501 TO OS-105, AND TEMP. RISER TO MH-21. THIS WILL ALSO INCLUDE THE INSTALLATION OF THE SPILLWAY, AND RIP RAP ASSOCIATED WITH EW-501. REFER TO THE EROSION AND SEDIMENTATION POLLUTION CONTROL NOTES AND DETAILS OF THIS PLAN SET FOR SPECIFIC SMP CONSTRUCTION SEQUENCES. WORK ASSOCIATED WITH INSTALLATION OF EW-501 IS GOVERNED BY CHAPTER 105 REGULATED ACTIVITIES. REFER TO THE GENERAL PERMIT FOR ADDITIONAL NOTES, DETAILS AND SEQUENCING FOR THIS INSTALLTION.

4.INSTALL TEMPORARY CONSTRUCTION FENCING AROUND SURFACE SMPS TO PREVENT THE SOIL FROM BEING COMPACTED BY VEHICLES.

5.BEGIN DEMOLITION AND REMOVAL OF EXISTING SITE FEATURES INCLUDING CLEARING AND GRUBBING.

6. ROUGH GRADE PROPOSED WETLAND REMEDIATION AREA. WORK ASSOCIATED WITH INSTALLATION OF THE PROPOSED WETLAND AREA IS GOVERNED BY CHAPTER 105 REGULATED ACTIVITIES. REFER TO THE GENERAL PERMIT FOR ADDITIONAL NOTES, DETAILS AND SEQUENCING FOR THIS INSTALLTION.

7.CONSTRUCT BERMS OR OTHER DIVERSION SYSTEMS TO DIVERT RUNOFF TO THE TWO SEDIMENT BASINS AS THE PRIMARY OPTION AND TO MINIMIZE RUNOFF TO THE PERIMETER SEDIMENT CONTROLS.

8.INITIATE THE NECESSARY EARTHWORK TO REACH THE GRADES INDICATED ON THE PLANS.

A. THE CONTRACTOR MUST PERFORM BULK OF EARTHWORK TO BALANCE CUTS AND FILLS TO THE GREATEST EXTENT POSSIBLE.
B. CONTRACTOR TO DEWATER EXISTING MAN-MADE STORMWATER MANAGEMENT PONDS PRIOR TO FILLING. ANY DEWATERING ACTIVITIES SHALL UTILIZE A PUMP WATER FILTER BAG IN ACCORDANCE WITH THE STANDARD DETAIL.
C. ALL AREAS DISTURBED DURING THE EARTHWORK PHASE OF CONSTRUCTION MUST BE TEMPORARILY SEEDED AND STABILIZED IN ACCORDANCE WITH THE GENERAL CONSERVATION NOTES AND SPECIFICATIONS AND SEEDING SPECIFICATIONS IF PERMANENT STABILIZATION CANNOT BE ACHIEVED WITHIN FOUR (4) DAYS.

STAGE II:

1.CONTINUE THE NECESSARY EARTHWORK TO REACH THE SUB-GRADES INDICATED ON THE DEVELOPMENT PLANS

A. ALL AREAS DISTURBED DURING THE EARTHWORK PHASE OF CONSTRUCTION MUST BE TEMPORARILY SEEDED AND STABILIZED IN ACCORDANCE WITH THE GENERAL CONSERVATION NOTES AND SPECIFICATIONS AND SEEDING SPECIFICATIONS IF PERMANENT STABILIZATION CANNOT BE ACHIEVED WITHIN FOUR (4) DAYS.
B. EARTHWORK SHALL BE PERFORMED PURSUANT TO THE PROCEDURES OUTLINED IN THE SOIL MANAGEMENT PLAN, WHICH MAY BE AMENDED BASED ON FINAL DESIGN PLANS.

2.INSTALL BUILDING FOUNDATIONS WHEN THE BUILDING PADS HAVE BEEN COMPACTED AND PREPARED. PERIMETER EARTHWORK CAN RUN CONCURRENT WITH INSTALLATION OF BUILDING FOUNDATIONS

3.INSTALL UTILITIES AND STORM SEWER PIPING AND STRUCTURES ASSOCIATED WITH THE STORMWATER MANAGEMENT SYSTEMS AS SHOWN ON THE PLANS STARTING WITH THE FURTHEST POINT DOWNSTREAM AND WORKING UP.

4.CRITICAL STAGE #2: INSTALL UNDERGROUND STORMWATER BASINS - AS AREAS ARE BROUGHT TO PROPOSED SUBGRADE ELEVATION, CONTINUE CONSTRUCTION OF ALL UTILITIES SHOWN ON THE STAGED PLANS, INCLUDING BUT NOT LIMITED TO SANITARY, STORM SEWER, WATER AND FIRE HYDRANTS, ELECTRIC, TELEPHONE, AND GAS. INSTALL INLET PROTECTION ON ALL NEW INLETS. PRIOR TO INSTALLATION OF ANY UPSTREAM STORMWATER SEWER STRUCTURES CONTRACTOR MUST CONNECT TO EXISTING TIE-IN POINTS, AS INDICATED ON THE PLANS. TRENCH EXCAVATION SHALL BE LIMITED TO THE LENGTH OF PIPE THAT CAN BE INSTALLED IN ONE (1) DAY; IF INSPECTION INDICATES THAT SOIL SEDIMENT HAS ENTERED ANY OF THE BASINS AND/OR STORM SEWERS, CLEANOUT AND/OR FLUSH THE INSTALLED SYSTEMS OF SEDIMENT.

5.CRITICAL STAGE #3: UPON 70% STABILIZATION OF UPSTREAM DRAINAGE AREA, DEWATER AND CONVERT SEDIMENT BASINS TO ABOVE GROUND BASINS.

A. REMOVE THE TEMPORARY BARREL, RISER, BAFFLES AND ACCUMULATED SEDIMENT AND EXCAVATE TO THE DEPTH AND SIZE REQUIRED.
B. ALL SIDES AND BOTTOM OF THE BED SHALL BE COVERED WITH CONTINUOUS NON-WOVEN GEOTEXTILE. PVC IMPERMEABLE LINER OR APPROVED EQUIVALENT SHALL BE PLACED BETWEEN THE LAYERS OF GEOTEXTILE. INSTALL ENDWALLS AND RIPRAP APRONS.
C. INSTALL PLANTING SOIL MIX AND PRE-SOAK THE PLANTING SOIL PRIOR TO PLANTING VEGETATION.
D. PLANT THE FACILITY WORKING FROM THE BOTTOM OF THE BASIN UP THE SIDES. SEEDING AND SHRUBS SHALL BE INSTALLED PER THE LANDSCAPING PLANS.
E. INSTALL EROSION CONTROL BLANKET AND INLET PROTECTION ON ALL NEW INLETS. REFER TO THE EROSION AND SEDIMENTATION POLLUTION CONTROL NOTES AND DETAILS OF THIS SET FOR SPECIFIC CONSTRUCTION SEQUENCES.

6.INLET PROTECTION AND SILT FENCE SHALL REMAIN IN PLACE UNTIL ALL DISTURBED AREAS ARE ADEQUATELY STABILIZED.

7.INITIATE FINAL GRADING BY PLACING 24" OF CLEAN FILL IN ALL PERVIOUS AREAS AND INSTALL PAVEMENT AND CONCRETE.

8. CRITICAL STAGE #4: INSTALL BANK STABILIZATION MEASURES ALONG THE DELAWARE RIVER AND THE PROPOSED WETLAND REMEDATION AREA. WORK ASSOCIATED WITH INSTALLATION OF THESE AREAS IS GOVERNED BY CHAPTER 105 REGULATED ACTIVITIES. REFER TO THE GENERAL PERMIT FOR ADDITIONAL NOTES, DETAILS AND SEQUENCING FOR THIS INSTALLTION.

8.INSTALL FINAL VEGETATION AND LANDSCAPING.

9.IF FOR ANY REASON STAGE II CONSTRUCTION IS NOT COMPLETED, THE SITE SHALL BE PERMANENTLY STABILIZED TO MIMIC THE EXISTING CONDITIONS. REFER TO PERMANENT STABILIZATION NOTES ON THE PLANS FOR DETAILS.

10. UPON PERMANENT STABILIZATION AND NOTIFICATION TO THE PADEP, REMOVE ANY REMAINING EROSION AND SEDIMENT CONTROL FACILITIES. ANY AREA DISTURBED DURING THE REMOVAL OF EROSION AND SEDIMENT CONTROL FACILITIES SHALL BE STABILIZED IMMEDIATELY.

11.CLEAR SITE OF DEBRIS AND ALL UNWANTED MATERIALS. OPERATOR SHALL REMOVE FROM SITE, RECYCLE OR DISPOSE OF ALL BUILDING MATERIALS AND WASTES IN ACCORDANCE WITH THE DEPARTMENT'S SOLID WASTE MANAGEMENT REGULATIONS AT 25 PA. CODE 260.1 ET SEQ., 271.1 ET SEQ. THE CONTRACTOR SHALL NOT ILLEGALLY BURY, DUMP OR DISCHARGE ANY BUILDING MATERIAL OR WASTE AT THIS SITE.

12. DEMOBILIZE.

13. A NOTICE OF TERMINATION FORM SHOULD BE SUBMITTED TO THE PADEP UPON STABILIZATION AND FINAL COMPLETION OF THIS PROJECT.

STANDARD SEQUENCE OF CONSTRUCTION NOTES

1. AT LEAST SEVEN (7) DAYS PRIOR TO ANY EARTH DISTURBANCE, THE INSPECTIONS COORDINATOR OF PWD (OFFICE: 215-685-6387) MUST BE CALLED TO SCHEDULE A PRECONSTRUCTION MEETING.

2. AT LEAST THREE (3) DAYS PRIOR TO (APPLICANT TO NAME EACH SMP) INSTALLATION, THE INSPECTIONS COORDINATOR OF PWD (OFFICE: 215-685-6387) MUST BE CALLED TO SCHEDULE AN INSPECTION (FOR EACH SMP).

3. ALL STONE THAT MAKES UP THE (APPLICANT TO NAME EACH INFILTRATION SMP) MUST REMAIN FREE OF SEDIMENT. IF SEDIMENT ENTERS THE STONE, THE CONTRACTOR MAY BE REQUIRED TO REMOVE THE SEDIMENT AND REPLACE IT WITH CLEAN-WASHED STONE.

4. UPON COMPLETION OF ALL EARTH DISTURBANCE ACTIVITIES AND PERMANENT STABILIZATION OF ALL DISTURBED AREAS, THE OWNER AND/OR OPERATOR SHALL CONTACT INSPECTIONS COORDINATOR OF PWD (OFFICE: 215-685-6387) FOR A FINAL INSPECTION PRIOR TO REMOVAL/CONVERSION OF THE E&S BMPS.

5. AS SOON AS SLOPES, CHANNELS, DITCHES, AND OTHER DISTURBED AREAS REACH FINAL GRADE, THEY MUST BE STABILIZED. CESSATION OF ACTIVITY FOR FOUR (4) DAYS OR LONGER REQUIRES TEMPORARY STABILIZATION.

6. THE NPDES NOTICE OF TERMINATION (N.O.T.) MUST BE SUBMITTED TO PA DEP UPON COMPLETION OF CONSTRUCTION (WHEN APPLICABLE).

7. WATER PUMPED FROM WORK AREAS SHOULD BE TREATED FOR SEDIMENT REMOVAL PRIOR TO DISCHARGING TO A "SURFACE WATER" (WHEN APPLICABLE).

MAINTENANCE PROGRAM

§102.4(b)(5)(x)

THE FOLLOWING MAINTENANCE PROGRAM HAS BEEN DEVELOPED TO PROVIDE FOR THE INSPECTION OF BMPs ON A WEEKLY BASIS AND AFTER EACH MEASURABLE RUNOFF EVENT, AND TO INCLUDE THE REPAIR OF THE BMPs TO ENSURE THEIR EFFECTIVE AND EFFICIENT

DEFINITION OF CLEAN FILL AND IMPORT/EXPORT MATERIAL NOTES

TO COMPLY WITH SECTION C.3 OF NOI

IF THE SITE WILL NEED TO IMPORT OR EXPORT MATERIAL FROM THE SITE, THE RESPONSIBILITY FOR PERFORMING ENVIRONMENTAL DUE DILIGENCE AND DETERMINATION OF CLEAN FILL WILL REST WITH THE APPLICANT.

1. CLEAN FILL IS DEFINED AS: UNCONTAMINATED, NON-WATER SOLUBLE, NON-DECOMPOSABLE, INERT, SOLID MATERIAL. THE TERM INCLUDES SOIL, ROCK, STONE, DREDGED MATERIAL, USED ASPHALT, AND BRICK, BLOCK OR CONCRETE FROM CONSTRUCTION AND DEMOLITION ACTIVITIES THAT IS SEPARATE FROM OTHER WASTE AND IS RECOGNIZABLE AS SUCH. THE TERM DOES NOT INCLUDE MATERIALS PLACED IN OR ON THE WATERS OF THE COMMONWEALTH UNLESS OTHERWISE AUTHORIZED. (THE TERM "USED ASPHALT" DOES NOT INCLUDE MILLED ASPHALT OR ASPHALT THAT HAS BEEN PROCESSED FOR RE-USE).

2. CLEAN FILL AFFECTED BY A SPILL OR RELEASE OF A REGULATED SUBSTANCE: FILL MATERIALS AFFECTED BY A SPILL OR RELEASE OF A REGULATED SUBSTANCE STILL QUALIFIES AS CLEAN FILL PROVIDED THE TESTING REVEALS THAT THE FILL MATERIAL CONTAINS CONCENTRATIONS OF REGULATED SUBSTANCES THAT ARE BELOW THE RESIDENTIAL LIMITS IN TABLES FP-1A AND FP-1B FOUND IN THE DEPARTMENT'S POLICY "MANAGEMENT OF FILL".

3. ANY PERSON PLACING CLEAN FILL THAT HAS BEEN AFFECTED BY A SPILL OR RELEASE OF A REGULATED SUBSTANCE MUST USE FORM FP-001 TO CERTIFY THE ORIGIN OF THE FILL MATERIAL AND THE RESULTS OF THE ANALYTICAL TESTING TO QUALIFY THE MATERIAL AS CLEAN FILL. FORM FP-001 MUST BE RETAINED BY THE OWNER OF THE PROPERTY RECEIVING THE FILL. A COPY OF FORM FP-001 CAN BE FOUND AT THE END OF THESE INSTRUCTIONS.

4. ENVIRONMENTAL DUE DILIGENCE: THE APPLICANT MUST PERFORM ENVIRONMENTAL DUE DILIGENCE TO DETERMINE IF THE FILL MATERIALS ASSOCIATED WITH THE PROJECT QUALIFY AS CLEAN FILL. ENVIRONMENTAL DUE DILIGENCE IS DEFINED AS: INVESTIGATIVE TECHNIQUES, INCLUDING, BUT NOT LIMITED TO, VISUAL PROPERTY INSPECTIONS, ELECTRONIC DATA BASE SEARCHES, REVIEW OF PROPERTY OWNERSHIP, REVIEW OF PROPERTY USE HISTORY, SANBORN MAPS, ENVIRONMENTAL QUESTIONNAIRES, TRANSACTION SCREENS, ANALYTICAL TESTING, ENVIRONMENTAL ASSESSMENTS OR AUDITS. ANALYTICAL TESTING IS NOT A REQUIRED PART OF DUE DILIGENCE UNLESS VISUAL INSPECTION AND/OR REVIEW OF THE PAST LAND USE OF THE PROPERTY INDICATES THAT THE FILL MAY HAVE BEEN SUBJECTED TO A SPILL OR RELEASE OF REGULATED SUBSTANCE. IF THE FILL MAY HAVE BEEN AFFECTED BY A SPILL OR RELEASE OF A REGULATED SUBSTANCE, IT MUST BE TESTED TO DETERMINE IF IT QUALIFIES AS CLEAN FILL. TESTING SHOULD BE PERFORMED IN ACCORDANCE WITH APPENDIX A OF THE DEPARTMENT'S POLICY "MANAGEMENT OF FILL".

5. WITH THE EXCEPTION OF SITES ENROLLED IN DEP'S LAND RECYCLING AND ENVIRONMENTAL REMEDIATION STANDARDS (ACT 2) PROGRAM AND SITES WITH DEP WASTE MANAGEMENT GENERAL PERMIT (WMGR096) APPROVAL TO USE REGULATED FILL, ALL FILL MATERIAL IMPORTED TO THE SITE MUST MEET THE DEFINITION OF CLEAN FILL, AS DEFINED IN THE NPDES STORMWATER CONSTRUCTION PERMIT. REGULATED FILL MAY ONLY BE USED ON ACT 2 SITES, IN ACCORDANCE WITH STANDARDS ESTABLISHED BY THAT PROGRAM, AND ON SITES WITH DEP GENERAL PERMIT WMGR096 APPROVAL.

6. THE PERMITTEE SHALL CONDUCT ENVIRONMENTAL DUE DILIGENCE TO VERIFY THAT SOILS EXCAVATED ON-SITE THAT IS USED TO ESTABLISH FINAL GRADE AND FILL IMPORTED TO THE PROJECT SITE IS CONSIDERED CLEAN FILL. IF DUE DILIGENCE RESULTS IN EVIDENCE OF A RELEASE, AS DEFINED IN DEP'S MANAGEMENT OF FILL POLICY (285-2182-773), THAT HAS AFFECTED THE FILL MATERIAL, THE PERMITTEE SHALL TEST THE MATERIAL TO DETERMINE WHETHER THE MATERIAL QUALIFIES AS CLEAN FILL, AND DEP'S ELECTRONIC FORM FP-001 (CERTIFICATION OF CLEAN FILL) MUST BE COMPLETED, RETAINED BY THE PERMITTEE OR THE PROPERTY OWNER ON-SITE, AND BE MADE AVAILABLE TO DEP/PWD UPON REQUEST.

7. IF THE PERMITTEE BECOMES AWARE DURING EARTH DISTURBANCE ACTIVITIES THAT SOILS IN THE AREA OF EARTH DISTURBANCE CONTAIN CONCENTRATIONS OF REGULATED SUBSTANCES EXCEEDING THE RESIDENTIAL MEDIUM-SPECIFIC CONCENTRATIONS FOR SOIL IN 25 PA. CODE CHAPTER 250, THAT WERE NOT PREVIOUSLY DISCLOSED TO DEP/CCD, THE PERMITTEE SHALL NOTIFY DEP/CCD IN ACCORDANCE WITH THE STANDARD CONDITION PART A II.D OF THE NPDES STORMWATER CONSTRUCTION PERMIT AND CEASE EARTH DISTURBANCE ACTIVITIES IN AREAS OF KNOWN SOIL CONTAMINATION UNTIL AUTHORIZED TO RESUME BY DEP/PWD

8. IF THE PERMITTEE ENCOUNTERS GROUNDWATER DURING EXCAVATION THAT THE PERMITTEE KNOWS OR HAS REASON TO BELIEVE IS CONTAMINATED BY ONE OR MORE POLLUTANTS AT CONCENTRATIONS EXCEEDING WATER QUALITY CRITERIA CONTAINED IN 25 PA. CODE CHAPTER 93, THAT WERE NOT PREVIOUSLY DISCLOSED TO DEP/CCD, THE PERMITTEE SHALL NOTIFY DEP/CCD IN ACCORDANCE WITH THE STANDARD CONDITION PART A II.D OF THE NPDES STORMWATER CONSTRUCTION PERMIT. CONTAMINATED GROUNDWATER MAY NOT BE PUMPED OR OTHERWISE DIVERTED TO SURFACE WATERS UNLESS SPECIFICALLY AUTHORIZED BY DEP/PWD

FILL MATERIAL THAT DOES NOT QUALIFY AS CLEAN FILL IS REGULATED FILL. REGULATED FILL IS WASTE AND MUST BE MANAGED IN ACCORDANCE WITH THE DEPARTMENT'S MUNICIPAL OR RESIDUAL WASTE REGULATIONS BASED ON 25 PA. CODE CHAPTERS 287 RESIDUAL WASTE MANAGEMENT OR 271 MUNICIPAL WASTE MANAGEMENT, WHICHEVER IS APPLICABLE. THE REGULATIONS ARE AVAILABLE ON-LINE AT WWW.PACODE.COM.

E&S PLAN PLANNING & DESIGN

§102.4(b)(4)

THE FOLLOWING MEASURES ARE TAKEN TO MINIMIZE THE EXTENT AND DURATION OF EARTH DISTURBANCE:
- ACCESS THE SITE THRU DESIGNATED CONSTRUCTION ENTRANCE
- PROTECT WOODLANDS WITH TREE PROTECTION FENCING
- SEQUENCE CONSTRUCTION ACTIVITIES BY LIMITING DISTURBANCES TO A SPECIFIC TASK SUCH THAT EACH TASK IS COMPLETED BEFORE THE NEXT TASK IS INITIATED

THE FOLLOWING MEASURES ARE TAKEN TO MAXIMIZE PROTECTION OF EXISTING DRAINAGE FEATURES AND VEGETATION:
- ACCESS THE SITE THRU DESIGNATED CONSTRUCTION ENTRANCE
- PROTECT WOODLANDS WITH TREE PROTECTION FENCING
- USE OF INLET PROTECTION FOR EXISTING DRAINAGE STRUCTURES

THE FOLLOWING MEASURES ARE TAKEN TO MINIMIZE SOIL COMPACTION:
- ACCESS THE SITE THRU DESIGNATED CONSTRUCTION ENTRANCE
- USE OF TREADED MACHINERY WHERE PRACTICAL DURING EARTHMOVING OPERATIONS
- GRADE SITE TO MINIMIZE EXTENT OF CUTS/FILLS

THE FOLLOWING MEASURES ARE TAKEN TO PREVENT OR MINIMIZE GENERATION OF INCREASED STORM WATER RUNOFF:
- DIRECT RUNOFF TO UNDERGROUND STORM WATER BASINS TO CONTROL RUNOFF RATES
- USE OF A WATER QUALITY STRUCTURE FOR WATER QUALITY REQUIREMENTS

E&S - GENERAL NOTES:

1. THIS PLAN REPRESENTS THE MINIMUM LEVEL OF IMPLEMENTATION OF TEMPORARY EROSION AND SEDIMENTATION CONTROL STRUCTURES. ADDITIONAL FACILITIES OR MEASURES SHALL BE INSTALLED WHERE NECESSARY OR WHERE DIRECTED BY EITHER THE TOWNSHIP OR THE COUNTY CONSERVATION DISTRICT AS CONSTRUCTION PROGRESSES.

2. THE OWNER/CONSTRUCTION MANAGER IS RESPONSIBLE FOR ALL TEMPORARY AND PERMANENT EROSION AND SEDIMENT CONTROLS AND SITE STABILIZATION. THE OWNER SHALL ASSIGN ONE INDIVIDUAL TO BE RESPONSIBLE FOR PROPER INSTALLATION AND MAINTENANCE OF ALL FACILITIES AND MEASURES.

3. PROTECTION TO THE EXISTING TREES AND SHRUBS SHALL BE TAKEN BY THE CONTRACTOR TO ELIMINATE UNNECESSARY DAMAGE.

4. ANY DRY FILL HAULED OFFSITE MUST BE TAKEN TO A LOCATION WITH AN EROSION AND SEDIMENTATION CONTROL PLAN WHICH HAS BEEN REVIEWED BY THE COUNTY CONSERVATION DISTRICT FOR ADEQUACY.

5. EROSION AND SEDIMENTATION CONTROLS MUST BE CONSTRUCTED, STABILIZED, AND FUNCTIONAL BEFORE SITE DISTURBANCE WITHIN TRIBUTARY AREAS OF THOSE CONTROLS.

6. STOCKPILES MUST BE STABILIZED IMMEDIATELY.

7. NO CHANGES SHALL BE MADE IN THE CONTOUR OF THE LAND. NO GRADING, EXCAVATING, REMOVAL OR DESTRUCTION OF THE TOPSOIL, TREES OR OTHER VEGETATIVE COVER OF THE LAND SHALL BE COMMENCED WITHIN A PROPOSED SUBDIVISION OR LAND DEVELOPMENT TRACT UNTIL SUCH TIME THAT A PLAN FOR SEDIMENTATION CONTROL AND MINIMIZING EROSION HAS BEEN REVIEWED AND FOUND SATISFACTORY BY THE COUNTY CONSERVATION DISTRICT AND REVIEWED AND APPROVED BY THE TOWNSHIP, OR THERE HAS BEEN A DETERMINATION BY THE TOWNSHIP, UPON RECOMMENDATION BY THE COUNTY CONSERVATION DISTRICT, THAT SUCH PLANS ARE NOT NECESSARY.

8. BEFORE INITIATING ANY REVISIONS TO THE APPROVED EROSION AND SEDIMENT CONTROL PLAN OR REVISIONS TO OTHER PLANS WHICH MAY AFFECT THE EFFECTIVENESS OF THE APPROVED E&S CONTROL PLAN, THE OPERATOR MUST RECEIVE APPROVAL OF THE REVISIONS FROM THE COUNTY CONSERVATION DISTRICT.

9. THE OPERATOR SHALL ASSURE THAT AN EROSION AND SEDIMENT CONTROL PLAN HAS BEEN PREPARED, APPROVED BY THE COUNTY CONSERVATION DISTRICT, AND IS BEING IMPLEMENTED AND MAINTAINED FOR ALL SOIL AND/OR ROCK SPOIL AND BORROW AREAS, REGARDLESS OF THEIR LOCATIONS.

10. CONTRACTOR SHALL USE TREADED MACHINERY AND MINIMIZE SOIL COMPACTION WHEREVER POSSIBLE.

GENERAL CONSERVATION NOTES AND SPECIFICATIONS

INTENT OF CONSERVATION PROGRAM: THE INTENT OF THIS PROGRAM IS TO PREVENT ACCELERATED EROSION OF THE EXPOSED SITE SOILS DURING THE CONSTRUCTION AND PERMANENT LIFE PERIODS OF THE DEVELOPMENT. THE PROGRAM REQUIRES RETENTION OF ALL SEDIMENTS ON THE CONSTRUCTION SITE TO MINIMIZE THE IMPACT OF DEVELOPMENT ON EXISTING STREAMS AND ADJACENT PROPERTY OWNERS. THESE OBJECTIVES WILL BE ACHIEVED BY MINIMIZING THE EXPOSURE TIME OF POTENTIALLY EROSIVE SOILS TO RUNOFF AND INSTALLATION OF THE TEMPORARY AND PERMANENT CONSERVATION PRACTICES IN PROPER SEQUENCE WITH CONSTRUCTION.
THE INTENT OF THIS PROGRAM SHOULD BE UNDERSTOOD AND IMPLEMENTED THROUGHOUT THE ENTIRE DEVELOPMENT. THE VARIOUS CONSTRUCTION TRADES SHOULD BE APPRISED OF THIS PROGRAM AND DIRECTED TO PREVENT UNDUE DISTURBANCE OF PREPARED AND PROTECTED SURFACES.

SURFACE STABILIZATION CRITERIA: ALL DENUDED SOIL SURFACES, INCLUDING SOIL STOCKPILES, ARE SUBJECT TO EROSION AND SHALL BE STABILIZED EITHER TEMPORARILY OR PERMANENTLY WITHIN TWENTY (20) DAYS, EXCEPT THE RESTORATION OF DRIVEWAYS, OFF-SITE UNDERGROUND UTILITY LINES AND GRADED PERIMETER AREAS SHALL BE ACCOMPLISHED WITHIN FIVE (5) DAYS. DURING NON-GERMINATION PERIODS, MULCH MUST BE APPLIED AT RECOMMENDED RATES. CRUSHED STONE ON PAVEMENT SUB GRADES IS CONSIDERED ADEQUATE PROTECTION. ALL DISTURBED ZONES AND VEGETATED REGIONS SHALL BE STABILIZED, PREFERABLY WITH A PERMANENT TREATMENT AS FOLLOWS:

A. TEMPORARY COVER ON DISTURBED AREAS: DISTURBED AREAS WHICH ARE NOT AT FINISHED GRADE AND WHICH WILL BE REDISTRIBUTED WITHIN ONE YEAR MAY BE SEEDED AND MULCHED WITH A TEMPORARY COVER. PREPARATION OF THE SURFACE, FERTILIZATION AND SEEDING WITH EITHER ANNUAL OR WINTER RYE GRASS SHALL BE DONE IN COMPLIANCE WITH THE CONSERVATION DISTRICT STANDARD FOR "TEMPORARY COVER FOR CRITICAL AREAS". GROUND LIMESTONE SHALL BE APPLIED AT THE RATE OF 100 LBS/1,000 S.F., THE FERTILIZER AND LIMESTONE SHALL BE WORKED INTO THE SOIL TO A DEPTH OF FOUR (4) INCHES PRIOR TO SEEDING. ANNUAL RYE GRASS SHALL BE APPLIED A RATE OF 1.5 LB/1,000 S.F. AND WINTER RYE AT A RATE OF 3.5 LBS/1,000 S.F. ALTERNATIVELY MULCHING WITH HAY OR STRAW (2-3 BALES/1,000 S.F.), NON-ASPHALTIC EMULSION, IN ACCORDANCE WITH THE CONSERVATION DISTRICT "MULCHING" MAY BE USED. MULCHING IS MOST APPLICABLE TO THOSE AREAS SUBJECT TO PERIODIC DISTURBANCE AND REWORKING. CONSERVATION DISTRICT STANDARDS FOR "PERMANENT SEED AND LEGUME COVER ON CRITICAL AREAS ON PREPARED SEED BED AND MULCHING", SHALL BE USED.

1.) GENERAL INFORMATION
A. DISTURBED AREAS ON WHICH EARTH MOVING ACTIVITIES HAVE CEASED AND WHICH WILL REMAIN EXPOSED FOR MORE THAN 20 DAYS MUST BE SEEDED AND MULCHED (INCLUDING STOCKPILES).
B. AREAS THAT FAIL TO GERMINATE MUST BE RESEEDED.
C. WHERE DISTURBED AREAS ARE DIFFICULT TO STABILIZE, NETTING SHOULD BE USED TO HOLD SEED AND MULCH IN PLACE; THIS IS ESPECIALLY IMPORTANT AROUND WATER COURSES, IN SWALES AND AREAS OF CONCENTRATED FLOWS, AND ON STEEP SLOPES.
D. ALL EROSION AND SEDIMENTATION POLLUTION (E&SP) CONTROLS MUST BE PROPERLY MAINTAINED AND CLEANED OF SEDIMENT WHEN NECESSARY, UNTIL THE SITE IS STABILIZED.
E. IF AT ANY TIME PRIOR TO SITE STABILIZATION ANY E&SP PROBLEMS OCCUR WHICH REQUIRE ADDITIONAL CONTROLS, IMMEDIATE ACTION MUST BE TAKEN TO CORRECT THE PROBLEMS.
F. NO SEDIMENT OR SEDIMENT LADEN WATER MUST BE ALLOWED TO LEAVE THE SITE WITHOUT FIRST BEING PROPERLY FILTERED.
G. ANY SEDIMENT THAT IS TRACED ONTO THE ROAD MUST BE CLEANED OFF BEFORE THE END OF THE DAY.
H. CONTRACTOR SHALL NOTIFY CONSERVATION DISTRICT OF DISPOSAL METHOD AND LOCATION OF EXISTING PAVING TO BE REMOVED FROM SITE.

II. STANDARD FOR STABILIZATION WITH MULCH

A. PERFORM ALL CULTURAL OPERATIONS AT RIGHT ANGLES TO SLOPE.
B. GRADE AS NEEDED AND FEASIBLE, SEE STANDARD FOR LAND GRADING.
C. PROTECTIVE MATERIALS TO BE USED:
1. UNROTTED SMALL-GRAIN STRAW OR HAY AT 3,0 TONS PER ACRE SPREAD UNIFORMLY AT 135 LBS/1,000 S.F. AND ANCHORED WITH LIQUID MULCH BINDER ON;
2. WOOD-FIBER OR PAPER-FIBER MULCH AT A RATE OF 1,500 LBS PER ACRE MAY BE APPLIED BY A HYDROSEEDER OR HYDROMULCHER. USE IS LIMITED TO FLATTER SLOPES AND DURING OPTIMUM SEEDING PERIODS IN SPRING AND FALL.
LIQUID MULCH BINDERS
APPLY IMMEDIATELY AFTER PLACEMENT OF HAY OR STRAW MULCH TO MINIMIZE LOSS BY WIND OR WATER. IF EMULSIFIED ASPHALT - (SS-1, CSS-1, CMS-2, MS-2, RS-1, RS-2, CRS-1, AND CRS-2), APPLY 0.04 GAL./SQYRD OR 194 GAL./ACRE ON FLAT SLOPES LESS THAN 8' HIGH. ON SLOPES 8' OR MORE HIGH, USE 0,075 GAL./SQYRD OR 363 GAL./ACRE.

III. STANDARD FOR LAND GRADING

A. DEFINITION
RESHAPING THE GROUND SURFACE BY GRADING TO PLANNED GRADES WHICH ARE DETERMINED BY TOPOGRAPHIC SURVEY AND LAYOUT.
NOTES:
1. PROVISIONS SHALL BE MADE TO SAFELY CONDUCT SURFACE WATER TO STORM DRAINS OR SUITABLE WATER COURSES AND TO PREVENT SURFACE RUNOFF FROM DAMAGING CUT FACES AND FULL SLOPES.
2. ADJOINING PROPERTY SHALL BE PROTECTED FROM EXCAVATION AND FILLING OPERATIONS.

B, INSTALLATION REQUIREMENTS
1. TIMBER, LOGS, BRUSH, RUBBISH, ROCKS, STUMPS AND VEGETABLE MATTER WHICH WILL INTERFERE WITH THE GRADING OPERATION OR AFFECT THE PLANNED STABILITY OR FILL AREAS SHALL BE REMOVED AND DISPOSED OF.
2. FILL MATERIAL IS TO BE FREE OF BRUSH, RUBBISH, TIMBER, LOGS, VEGETATIVE MATTER AND STUMPS IN AMOUNTS THAT WILL BE DETRIMENTAL TO CONSTRUCTING STABLE FILLS,
3. ALL FILLS SHALL BE COMPACTED SUFFICIENTLY FOR THEIR INTENDED PURPOSE AND AS REQUIRED TO REDUCE SLIPPING, EROSION OR EXCESS SATURATION.
4. ALL DISTURBED AREAS SHALL BE LEFT WITH A NEAT AND FINISHED APPEARANCE AND SHALL BE PROTECTED FROM EROSION.
5. (SEE I.A.).
IV STANDARD FOR PERMANENT STABILIZATION WITH SOD

A. METHODS AND MATERIALS
1. CULTIVATED SOD IS PREFERRED OVER NATIVE OR PASTURE SOD, SPECIFY "CERTIFIED SOD" OR OTHER HIGH QUALITY CULTIVATED SOD.
2. SOD SHOULD BE FREE OF WEEDS AND UNDESIRABLE COARSE WEEDY GRASSES,
3. SOD SHOULD BE OF UNIFORM THICKNESS, APPROXIMATELY 5/8 INCH, PLUS OR MINUS 1/4 INCH, AT TIME OF CUTTING, (EXCLUDES TOP GROWTH).
4. SOD SHOULD BE VIGOROUS AND DENSE AND BE ABLE TO RETAIN ITS OWN SHAPE AND WEIGHT WHEN SUSPENDED VERTICALLY WITH A FIRM GRASP FROM THE UPPER 10% OF THE STRIP. BROKEN PADS OR TORN AND UNEVEN ENDS WILL NOT BE ACCEPTABLE.
5. FOR DROUGHTY SITES A SOD OF KENTUCKY 31 TALL FESCUE AND BLUEGRASS IS PREFERRED OVER A STRAIGHT BLUEGRASS SOD.
6. ONLY MOIST, FRESH, UNHEATED SOD SHOULD BE USE. SOD SHOULD BE HARVESTED, DELIVERED AND INSTALLED WITHIN A PERIOD OF 36 HOURS.
B. SITE PREPARATION (SEE STANDARD FOR LAND GRADING)
C. SOIL PREPARATION (SEE SPECIFICATION FOR SEEDING & SOIL TREATMENT FOR PERMANENT VEGETATIVE COVER),
D. SOD PLACEMENT
1. SOD STRIPS SHOULD BE LAID ON THE CONTOUR, NEVER UP AND DOWN THE SLOPE, STARTING AT THE BOTTOM OF THE SLOPE AND WORKING UP. ON STEEP SLOPE, THE USE OF LADDERS WILL FACILITATE THE WORK AND PREVENT DAMAGE TO THE SOD, DURING PERIODS OF HIGH TEMPERATURE, LIGHTLY IRRIGATE THE SOIL IMMEDIATELY PRIOR TO LAYING THE SOD.
2. PLACE SOD STRIPS WITH SNUG EVEN JOINTS THAT ARE STAGGERED, OPEN SPACES INVITE EROSION,
3. ROLL OR TAMP SOD IMMEDIATELY FOLLOWING PLACEMENT TO INSURE SOLID CONTACT OF ROOT, MAT AND SOIL SURFACE, DO NOT OVERLAP SOD. ALL JOINTS SHOULD BE BUTTED TIGHTLY IN ORDER TO PREVENT VOIDS WHICH WOULD CAUSE DRYING OF THE ROOTS,
4. ON SLOPES GREATER THAN 3:1, SECURE SOD TO SURFACE SOIL WITH WOOD PEGS, WIRE STAPLES, OR SPLIT SHINGLES (8 TO 10 INCHES LONG BY 3/4 INCH WIDE).
5. SURFACE WATER CANNOT ALWAYS BE DIVERTED FROM FLOWING OVER THE FACE OF THE SLOPE, BUT A CAPPING STRIP OF HEAVY JUTE OR PLASTIC NETTING, PROPERLY SECURED, ALONG THE CROWN OF THE SLOPE AND EDGES WILL PROVIDE EXTRA PROTECTION AGAINST LIFTING AND UNDERCUTTING OF SOD. THE SAME TECHNIQUE CAN BE USED TO ANCHOR SOD IN WATER - CARRYING CHANNELS AND OTHER CRITICAL AREAS. WIRE STAPLES MUST BE USED TO ANCHOR NETTING IN CHANNEL WORK.
6. IMMEDIATELY FOLLOWING INSTALLATION, SOD SHOULD BE WATERED UNTIL MOISTURE PENETRATES THE SOIL LAYER BENEATH SOD TO A DEPTH OF 4 INCHES. MAINTAIN OPTIMUM MOISTURE FOR AT LEAST TWO WEEKS.
E. TOPDRESSING
IF SLOW RELEASE NITROGEN (300 LBS 38-0-0 PER ACRE OR EQUIVALENT) IS USED IN ADDITION TO SUGGESTED FERTILIZER, THEN A FOLLOW-UP OF TOPDRESSING IS NOT MANDATORY.
1. SPRING INSTALLATION OF SOD WILL REQUIRE AN APPLICATION OF FERTILIZER SUCH AS 10-20-10 OR EQUIVALENT AT 400 LBS/ACRE OR 10 LBS/1,000 S.F. BETWEEN SEPTEMBER 1 AND OCTOBER 15.
2. FALL INSTALLATION OF SOD WILL REQUIRE THE ABOVE BETWEEN MARCH 15 AND MAY 1.

V. SPECIFICATION FOR SEEDING & SOIL TREATMENT FOR PERMANENT VEGETATIVE COVER

A. SITE PREPARATION
1. GRADE AS NEEDED AND FEASIBLE TO PERMIT THE USE OF CONVENTIONAL EQUIPMENT FOR SEEDBED PREPARATION, SEEDING, MULCH APPLICATION AND ANCHORING, AND MAINTENANCE.
2. SUBSOIL SHOULD BE TESTED FOR LIME REQUIREMENT AND LIMESTONE, IF NEEDED SHOULD BE APPLIED TO BRING SOIL PH TO 6.5 AND INCORPORATED INTO THE SOIL AS NEARLY AS PRACTICAL TO A DEPTH OF 4 INCHES.
3. IMMEDIATELY PRIOR TO TOPSOIL DISTRIBUTION, THE SURFACE SHOULD BE SCARIFIED TO PROVIDE A GOOD BOND WITH THE TOPSOIL.

B. APPLYING TOPSOIL
1. TOPSOIL SHOULD BE HANDLED ONLY WHEN IT IS DRY ENOUGH TO WORK WITHOUT DAMAGING SOIL STRUCTURE.
2. A UNIFORM APPLICATION TO A DEPTH OF 5 INCHES (UNSETTLED) IS RECOMMENDED. SOILS WITH A PH OF 4,0 OR LESS OR CONTAINING IRON SULFIDE SHALL BE COVERED WITH A MINIMUM DEPTH OF 12 INCHES OF SOIL HAVING A PH OF 5.0 OR MORE.
C. SEEDBED PREPARATION
1. PERFORM ALL CULTURAL OPERATIONS AT RIGHT ANGLE TO SLOPE.
2. APPLY 10-20-10 OR EQUIVALENT RATED FERTILIZER AT A RATE OF 500 LBS/ACRE OR 11 LBS/1,000 S.F.
3. APPLY 300 LBS 38-0-0/ACRE OR EQUIVALENT OF SLOW RELEASE NITROGEN.
4. APPLY PULVERIZED DOLOMITIC LIMESTONE AT A RATE OF 1/3 TONS/ACRE OR 135 LBS/1000 S.F.
5. WORK LIME AND FERTILIZER INTO THE SOIL AS NEARLY AS PRACTICAL TO A DEPTH OF 4 INCHES. CONTINUE TILLAGE UNTIL A REASONABLY UNIFORM FINE SEEDBED IS PREPARED.
